

INDEX

TO

VOLUME I.—MDCCCXXXV—XXXVI.

A

- Anæmia, crushing of, 18.
 Abdominal tumours, 180.
 Abercrombie, Dr. degree of, 641.
 Abscess in the perineum, 295.
 Aphalocyst of the brain, 45.
 Acne indurata, creosote in, 193.
 Acromium as an emmenagogue, 86.
 Adler, suicide of, 63.
 Advertisment, professional, 337; of quack pills, 380.
 Air-pump in strangulated hernia, 58.
 Aldersgate School of Medicine, 5.
 Allis's Clinical Reports, 110.
 Almanack, British Medical, 392.
 Alexander, Dr., on infantile remittent fever, 99, 293.
 Anaæstrosis from suppressed passion, 569.
 Anæstrosia, sinapisms to the mamma in, 174.
 Amputation, below the knee, 95; of the arm, 17.
 Amputations at Breslau, 57.
 Anæsthetic, M., on artificial anus, 256; on traumatic hæmorrhage, 350.
 Anæsthesia, idiopathic, 436; with other diseases, 685.
 Anatomy in Ireland, 677.
 Anstey, Professor, course of lectures by, on *Diseases of the Brain and Nervous System*:—
 LECTURE 1.—*Introduction*.—The peculiar difficulties which surround the investigation of nervous diseases; points to be weighed in considering the causes of these diseases; their complication with other diseases; extreme obscurity of their pathology; modern changes in their character; the causes of observation errors in their study; difficulties added by the disposition to theorize; use of the nervous force not generally marked; different changes or lesions in the brain, producing nearly identical symptoms; the brain not a single organ, but composed of a vital unity; difficulties of investigation caused by idiosyncrasies, by the same lesion of the brain producing the most varied symptoms, and by the complications of sympathy;

modifying influence of age; the great majority of the diseases of the nervous system present no perceptible changes of structure; reasons why pathological anatomy is at fault; chemical and nutritive changes of the brain; indications of the treatment of nervous diseases; influence of imagination; means of clearing obscure points in the pathology of the nervous system; order and spirit to be observed in the present course of lectures, 353.

LECTURES 2 and 3.—*Congestion of the Brain*.—The various anatomical or pathological characters of cerebral hyperæmia; considerations to be observed in examining its morbid appearances; influence of atmospheric temperature in producing cerebral congestion; other atmospheric effects; effects of stimulants and narcotics on the brain; cerebral congestion from diseases within the brain; from affections of other organs; from venereal pleasure and abstinence, age, and mechanical forces; general symptoms of cerebral congestion; first variety, *stiform*; second, or *coup de sang*; third, hemiplegia; fourth, paralysis; fifth, furious delirium; different symptoms of cerebral disease; attempt to localize the cerebral functions; confusion and other affections of the cerebellum; congestion of the spinal marrow; terminations of cerebral congestion; indications of treatment, 393.

LECTURE 4.—*Encephalitis*.—The most striking phenomena in the disturbed functions; lesions of the digestive and circulatory apparatus; lesions of respiration; modifications of symptoms; the three varieties of acute encephalitis; practical importance of this division; duration and termination of the disease; treatment by bleeding and cold; different modes of applying cold; revulsives and purgatives; mercury is alone a specific in inflammation? character of the chronic form of the disease; chronic inflammation of the cerebellum. (Note to this lecture)—

the term *encephalitis*, symptoms simulating the disease; three divisions; its anatomical characters and causes, 681.

LECTURE 5.—Myelitis, or Inflammation of the Spinal Marrow.—Division into acute and chronic; anatomical characters, and parts which it attacks; causes and symptoms; lesions of motility; lesions of sensibility in the neighbourhood of the spine; in distant parts; diminution of sensibility in the disease; difficulty of deglutition and articulation; derangement of the digestive functions; of the circulation and respiration; modifications of the secretions; effects of the disease on the organs of generation; diagnosis; diseases simulating irritation of the spinal marrow, according to the views of Messrs Griffin and Ens; duration, termination, and treatment of myelitis, 473.

LECTURE 6.—Anemia of the Brain and Cerebral Hemorrhage.—(1. *Anemia*).—Its simulation of hyperemia; anatomical characters; symptoms; delirium; delirium from withdrawing stimulants; disturbance of sensibility and motility; treatment.—(2. *Cerebral Hemorrhage*).—Impropriety of using the term *apoplexy*; parts of the brain in which it occurs; meningeal apoplexy; sanguineous cerebral cysts; appearance and source of the effused blood; period when cicatrization is effected; state of the brain near the effusion, of its mass, and of the membranes; causes and periods of cerebral hemorrhage; influence of a diminished aortic caliber; changes in the venous circulation; general plethora; sex and age, 521.

LECTURE 7.—Cerebral Hemorrhage (continued).—Symptoms of actual effusion; premonitory symptoms; the disease without them; symptoms depending on other morbid changes than effusion; case of effusion without a symptom of that lesion; paralysis as a symptom; case without paralysis; intermitting paralysis; hemorrhage into the cerebral hemispheres; hemiplegia and its indications; sixteen cases of hemiplegia occupying the same side of the body as the lesion in the brain; inquiry into the portions of the brain severally influencing the upper and lower extremities; effusion upon the brain as affecting motility; lesions of the *pons varoli*.

LECTURE 8.—Cerebral Hemorrhage (continued).—*Lesions of Motility and Sensibility.*—Does paralysis follow this lesion? On which side is it?—thirty-two cases of this lesion; which lobes the effusion occupies; hemorrhage into both cerebrum and cerebellum; effusion of blood into the spinal marrow; paralysis of muscles of the eyes and cheeks;

order of its disappearance; lesions of sensibility in the brain itself; modifications of sensibility in the skin and mucous membranes; disturbance of the organs of various portions of the brain particularly affected; blindness from the disease; modifications of hearing, 601.

LECTURE 9.—Cerebral Hemorrhage (continued).—*Lesions of Intelligence.*—Lesions giving premonitory symptoms; alteration of the intellectual faculties at the moment of effusion; differences in the seat and extent of hemorrhage; no such lesion in spinal hemorrhage; state of the intellect after the effusion; affections of the speech, circulation, respiration, and generative organs in cerebral hemorrhage, 649.

LECTURE 10.—Cerebral Hemorrhage (concluded).—*Peculiar Varieties.*—Symptoms attending cerebral hemorrhage, which do not seem characteristic of the first class of symptoms; contraction and spasmodic affections of the limbs; their treatment; impulses to advance and retreat; delirium and somnolency attending apoplexy; symptoms uncommon with cerebral lesions; duration and progress of apoplexy; other varieties; treatment; abuse of venesection, autotomy, leeches, and revulsives; treatment of paralysis, especially; prevention of apoplexy; hypertrophy of the brain, 721.

LECTURE 11.—Hypertrophy of the Nervous Centres.—Anatomical character of hypertrophy of the cerebrum; cerebral hypertrophy, with and without enlargement of the cranium; causes favoring the lesion; periods of occurrence, and symptoms; lesions of intelligence, sensibility, motility, respiration, and circulation, in cerebral hypertrophy; its divisions into the chronic and acute periods; varieties and treatment; partial hypertrophy of the cerebrum; hypertrophy of the cerebellum, and its influence on the genital apparatus; hypertrophy of the spinal marrow, 761.

LECTURE 12.—Atrophy of the Brain and Spinal Marrow.—General description of its division into congenital and gradually acquired atrophy; great diminution of the nervous centres; symptoms and changes in the osseous parietes; c. hydrocephalus as one form; c. hernia following atrophy; atrophy of the brain normal but very small; atrophy from deposits in the brain; the brain most liable to atrophy; atrophy of the cerebrum in particular; parts above and below the lateral clefs; entire absence of the cerebral lobes; absence of

B

- Empyema, lecture on, by Dr. Roe, 288; par-**
tisanteritis thoracis in, 288.
Encephalitis, acute, symptoms of, 426; vari-
eties, 426; treatment, 428; chronic, causes
and symptoms of, 430.
Entomology, 143.
Epilepsy, from injury of the head, 200;
modified, case of, 697.
Enterolithus, case of, 963.
Epps, Dr., letter from, 319; on monopolies
in medical education, 315.
Epulis, clinical lecture on, by Sir B. Brodie,
277.
Erinensis on the conduct of the Royal Dublin
Society, and the proceedings of Ministers,
978.
Erysipelas, nitrate of silver in, 322; compli-
cated, fatal case of, 322; lecture by Mr.
Liston on, 324; puncture in, 327; of the
head, case of, remarkable effects of the ex-
tract of belladonna in, 758, 806.
Errata, 16, 128, 160, 224, 271, 320, 341, 472,
647, 728, 759, 808, 888.
Erythema, characters of, 324.
Evelt, Mr., note from, 759.
Exfoliation of bone, reproduction after, 646.
Extra-uterine rotation, discussion on a case
of, 217; Dr. Ramsbotham's letter on, 266.
Extravasation of urine, from external injuries,
19; in children, 20; local differences be-
tween, into cellular and serous tissues, 22.
- F**
- Facial nerve, section of, by disease, 45.**
Faraday, Mr., on the silicification of plants,
756.
Farnham, inquest at, 257, 263, 345, 351.
Farr, Mr., lectures by, on hygiene, 240, 773.
Features, artificial, 533.
Feces and urine, non-secretion of, during
many years, 702.
Fergusson, Dr., on medical aid for the sick
poor, 747.
Ferral, Mr., note respecting, 919.
Fever, nature and causes of, 131; conva-
lescence from, followed by death, 268; treat-
ment of, Dr. Bright on, 596.
Fieschi, head of, 936.
Fingers, contraction of, 622.
Flame, nature and qualities of, 360.
Fleishmann, Dr., on belladonna as a preserva-
tive against scarlatina, 300.
Flogging, death from, 875.
Food of plants and animals, changes of, 163.
Fosbroke, Dr., on diseases of the heart, 438,
629.
Fox, Mr., on the election of parochial medi-
cal officers, 941.
Fractures, bad effects of splints and tight
bandages in, 168, 245, 288; treatment of,
without splints, 461; Mr. Wardrop on,
without splints, 710; Dr. Wallace on, 627;
Mr. Sherwin on, 498; of the tibia, cured
without splints, 248; of the tibia and
fibula, and of the femur, similarly treated,
240; bleeding in cases of, 200; the
head of the scapula, 270; of the tibia and
fibula, with paralysis, 533; treatment of,
384, 423; death after, 384; amputation of the
leg, followed by gangrene, 615; of the jaw
cases of, 741; of the patella, new mode of
treating, 783; of the olecranon, 807; of
the thigh, 807.
Free Hospital, Greville-street, proceedings at,
340, 944, 981.
Fungus medullaris, of the pelvis, 695; malign-
ant, of the penis and groin, 694.
Furlong, Dr., case by, of modified epilepsy,
697.
- G**
- Gangrene, senile, case of, 371; of the lungs**
in the insane, 793.
Gastritis, chronic, case of, 458.
Gastrodynia, creosote in, 124, 270.
Gazette Medicale, January 1836, 772.
Guardians, boards of, contracts of, 509, 803.
Generation of living and dead matter, 105.
Genital organs, effects of hypertrophy of the
cerebellum on the, 765.
Geohagan, Dr., on poisoning by hydrocyanic
acid, 175.
Gerson, Dr., on traumatic cataract, 43.
Gibson, Mr., case by, of spasmodic colic,
563.
Girtten, Mr., on ancient and modern black
nations, 40.
Glanders treated with creosote, 594.
Glotus, scalded, cases of, 903.
Goitre, lymphatic, ligation of thyroid arteries
in, 252.
Gonorrhoea, cases of, with condylomata, 125,
157, 593; in the female, 455; creosote in,
455; nitrate of silver in, 499.
Gonorrhoeal rheumatism, Mr. Samuel on,
746.
Gouty concretions, case of, 821.
Gowing, Mr., case by, of strangulated ingui-
nal hernia, 699.
Goyraud, Dr., on inguino-intestinal hernia,
450.
Granger, Mr., present to, from his pupils,
883.
Green, Mr., on the use of setons in hydrocele,
334; lecture by, on fatal simple fracture of
the leg, 615.
Green, Dr. P. H., cases and remarks by. (See
Hopital des Enfants.)
Gregory, Dr., report by, on small-pox and
vaccination, 831.
Gregory's Conspectus, by Dr. Venables, 209.
Grinestone, Mr., puff of, 52.
Grisolle, M., on colic from lead, 52.
Guislain, M., on gangrene of the lungs in the
insane, 793.
Gum diseases, synopsis of, 983.
Guthrie, Mr., operation by, 983.
Guy's Hospital, 160; reports, 598
to the Staff from, 920; obstetric, 983.

H

- Haech, M., on pericarditis, 796.
 Hakkenmanism in London, 755, 787, 840; doctrines of, 932.
 Halford's, Sir H., puff by, of Mr. Battley, 123.
 Hamilton, Dr., the late, 381.
 Hancock, Dr., note from, 801.
 ● Hawkins, Mr., on the skull of Dean Swift, 503.
 Hemorrhage, into the arachnoid, 45; traumatic, researches in, 450; of the cerebellum, 601; cerebral, peculiar varieties of, M. Andral on, 729; from the mouth, severe case, 863; ligatures in, 934.
 Hemorrhoid in the rectum, 295.
 Head, pain in, treated with carbonate of iron and hydriodate of potash, 274; injury of, 518.
 Heart, case of disease of, 229; disease of, following rheumatism, 235; disease of, elucidating difficulties of diagnosis, 458; sounds and motions of, 501; Dr. Fosbrooke on diagnosis of diseases of, 620; movements of, 827; Mr. Bryan on the sounds of 866; atrophy of the valves of, 916.
 Becker's Annalen, articles in, 58; Vol. 2, Nos. 3 and 4, Vol. 3, No. 1, 867.
 Heidelberg, hospital statistics at, 981.
 Heifer, the, early breeding in, 576.
 Hemiplegia, M. Andral on, 401, 557.
 Hemming on uterine diseases, 141.
 Hentsch and Tweedie, Messrs., proceedings against, 840, 914; letters from, 981.
 Hermaphroditism, an instance of, 375; in an orang-outang, 965.
 Hernia, inguinal strangulated, 15, 75, 90, 155, 669; strangulated, cured with the air-pump, 58; heater in umbilical, 57; strangulated femoral, 153; memoir on inguino-intestinal, 450.
 Hip-joint, diseases of, lectures on, 482, 528.
 Hirsch, Dr., on thymic asthma, 201.
 Hippocrates, life and doctrines of, 773.
 Hodgson, Mr., case by, of phlegmasia dolens, 73.
 Hone, Sir E., one of the caustic bougie cases of, 770.
 Hooper, Mr., note from, 349.
 Horse, loss of the tongue in, 626.
Hopital des Enfants Malades, Paris, cases at, and remarks on, by Dr. Green:—Croup, 29; tracheotomy in croup, 29; autopsy in croup, 31; laryngo-tracheitis mistaken for, 54; meningitis of the convexity of the brain, 56; of the base of the brain, 37; tubercular meningitis in a child after measles, 492; tubercular meningitis in a child after measles and phthisis, 573; tubercular meningitis preceded by small-pox, 780; tubercular meningitis terminating in acute hydrocephalus, 781; typhus fever in the same, 859, 901; choroid pathology and, 937; pleuro-pneumonia with

- pericarditis, 939; lobular pneumonia with laryngitis and bronchitis, 940.
 Hospital irresponsibility, 139; functionaries, attendance of, 668; Samaritan Society, 756.
 Hospitals and Schools of Medicine, in London, list of, open to students in the session 1835-36, 1.
 Hourmann and Dechambre, M.M., on the diseases of old persons, 705.
 House of Commons, discussion on the Medical Witnesses Bill in, 905; remarks on discussion at, 913.
 House-surgeon, election of one, by concours, 909.
 Huteland's Journal, 500; elixir for catarrh, 264.
 Humerus, dislocation of, on the dorsum scapulae, 758.
 Hunterian Theatre of Anatomy, 7.
 Hydriodate of potash, in pain of the head, 274; in lupiform syphilis, 628; in syphilis, 743; in malignant, fungous, and cancerous diseases, 894.
 Hydrocele, 95; treated with seton, 331.
 Hydrocephalus, acute, of Abercrombie, 37.
 Hydrocyanic acid, poisoning by, 174.
 Hydrophobia, case frequently simulating, 25; remarks on the article of Mr. Youatt on, by Mr. Varenne, 26.
 Hygiene, lecture on, 240; history of, 775.
 Hygienists of old, 241.
 Hypertrophy of the cerebrum and cerebellum, 761 (see Andral, M.); Dr. Carswell on, 967.

I

- Idin, Mr., case by, of amaurosis, 569.
 Ilium, disease of the bones of, 517.
 Illusion of the mind, in delirium tremens, 227.
 Infants, remittent fever of, 99, 293; diminution of mortality of, 691; scalded glottis in, 958.
 Inflammation, Mr. Searle on, 26; and morbid vascularity, 311; and fever, Dr. Row on, 931.
 Inglis, Dr., on cases mistaken for croup, 497; on a case of aphonia, 903.
 Inquest, verdict at, without evidence, 88; at Farnham, 257, 263; on a fatally-flogged soldier, 875.
 Insane, abolition of irons in the treatment of the, 457; gangrene of the lungs in, 793.
 Insanity, following wounds of the head, 828.
 Instinct of animals, 107.
 Instruction, clinical, Mr. Travers on, 276.
 Intellect, derangement of, from sabre wounds of the head, 828.
 INTERCEPTED LETTERS:—
 Retreat into the country; thoughts at a distance from the profession; affairs at Windsor; changes in medical practice; country amusements: royal fun: the

markets; Dr. Wardrop on bleeding, 348.

Caution to the aged; aspirants for the collegiate chair; the hospital schools; the guinea trade; Dr. Wardrop's book; nice discrimination in V.S., 383.

New source of terror to the medical monopolists; the real Hawkins; Madame V., 471.

The new oration; the elevation of Dr. Paris; the revolutionary University; deputations and their answer; high moral mode of libelling, 572.

Arrival in Mayfair; rural retrospect; book for the library; town prospects; the new terror, 590.

Letter from Rodeick; the new terror; Sir Benjamin's speculation; precise state of the Journal of fabrications; recovery of missing property, 721.

The contrast; Lincoln's-inn-fields news; the new University; the Pall Mall East meetings, 801.

Intestine, excision of two feet of, 45; distinction between inferior and superior orifices of, 45; wound of, 94.

Intestinal concretions, case of, 965.

Itch insects, detection of, 251.

Iodine in diabetes, 319; in the urine, 970.

Ipswich, coronership of, 599.

Ireland, medical reform in, 308, 379; anatomy in, 877; medical coroners in, 878.

Iris, physiology of, 109.

Iron, supersulphate and superacetate of, in neuralgia, leucorrhœa, and night perspiration, 102.

J

Jacob, Dr., on comparative anatomy, 211.

Jacob, Mr., 213.

Jatropha curcas, purgative qualities of, 916.

Jaw, fractures of the, 741; osteo-sarcoma of, and removal, 887.

✓ Jervis-street Hospital, Dublin, cases and remarks at, by Dr. Wallace:—Treatment of fractures of the leg and thigh-bones of children without splints, 627; cure of lupiform syphilis with the hydriodate of potash, 628; contraction of the fingers, after diffuse inflammation of the fore-arm, 628; prolapsus ani, its pathology and treatment, 635; fractures of the jaw, 741; syphilis treated with hydriodate of potash, 743; disorganization of tissues of the calf, 743; secondary syphilis, contagion of, 805; ulcerated surfaces, 805; locked-jaw resulting from injured nerves, 846; cases of tetanus, 846; hydriodate of potash in malignant, fungous, and cancerous diseases, 891; cases of scalded glottis treated with calomel, operation of bronchotomy in the same injury, 938.

Jewel, Dr., on nitrate-of-silver injections in gonorrhœa and leucorrhœa, 499.

Jones, Sir W., on ancient and modern negroes, 40.

K

Kelso, Dr., on catalepsy complicated with hysteria, 23; on a case of small-pox complicated with hysteria, 744; on the epidemic small-pox at Lisburn, 744.

King, Mr., on the University of London and the College of Surgeons, 16, 261; on remuneration at coroners' inquests, 950.

Kingdon, Mr., exclusion of, from the College Council, 186; letter of, to the medical profession, 183; and Mr. Lawrence, 210; College Council note respecting, 267; consolatory address to, 315.

King's College Medical School, 7, 345; letter from a student of, 420; and Charing-Cross Hospital, 647; chair of materia medica at, 680; note from Dr. Ritchie respecting, 724; exclusion of men of science from, 917, 931.

Kingston, Dr., on atrophy of the valves of the heart, 946.

Kinnerton-street School, 472.

Kluge, Dr., on inflammation of the lungs in infants, 42.

✓ Kirby, Mr., resignation of, 379, 418.

Kirby's Bridgewater Treatise, review of, 105.

Kirby, Dr., on a new mode of treating croup, 173.

Knee-joints, diseases of, 528; diseases of the ligaments of, and disease simulating them, 609.

Knowllys, Mr. Newman, on a law of coroners' inquests, 943.

Kopp's asthma, 301.

Kranfus, Dr., case by, of caesarean section, 701.

L

LANCET, THE, present volume of, 113, 192, 352; "occasional" letters in, 212.

Langstaff, Mr., on cases of diseased testicle, 405.

Laryngitis, bronchitis, and lobular pneumonia, 940.

Larynx, ulceration of, 74.

Latham, Dr., case-book of, 51, 213.

Laurie, Sir Peter, vote of, at Christ's Hospital, 184.

Lawrence, Mr. W., fate of, 186.

Lead, acetate of, poisoning by, 93.

Lebaudy's Surgical Anatomy, 144, 189.

Lecture and ticket system, 12, 579.

Lecturing, the system of, 89.

Lee, Mr., on the continental schools, 147.

Lelet, M., on false membranes of the arachnoid, 792; account of Fieschi's head by, 936.

Leucorrhœa, supersulphate and superacetate of iron in, 102.

Lichtenstadi, Professor, on anatomy, 102.

Life, grades of, and animal structure, 102.

Ligatures to bleeding vessels, 936.

Lindsay, Mr., case by, of obstructed bowels, 361; operation by, for a new anus, 505.

- Liston, Mr., clinical lectures of, 125. (See also *North-London Hospital*).—On stricture, 755, 767, 816; conduct of pure surgeons in the College Council to, 752.
- Litchfield, Dr., on the itch insect, 251.
- Lithotomy, cases of, 123, 152, 160, 320; at Breslau, 56; at Naples, 255; anomalous case of, by Mr. Lizars, 708.
- Liver, diseases of, Conwell on, 206; disease of, with abscess, 256.
- Lizars, anomalous operation of lithotomy by, 708.
- Lock Hospital, cases of gonorrhœa with condyloma at, 125, 157, 598.
- London University, and North-London Hospital, 5.
- London Hospital, 160.
- London Medical Society, 150.—Abdominal tumours, 180; Casarean operation fourteen months after conception, 181; discussion on, 217; cyst in the thyroid gland, 219; letter from Dr. Ramsbotham on report of case of extra-uterine foetation, 266; chimney-sweeper's cancer, 512; tuberculated disease of the uterus, 513; consolatory address to Mr. Kingdon, 315; treatment of bronchitis, 337; ringworm, 357; death from Monson's pills, 338; artificial fractures, 338; treatment and effects of fractures, 384; treatment of fractures, 461; gonorrhœal rheumatism, 462.
- Lowenhard, Dr., case by, of sciatica, 301.
- Lungs, inflammation of, in new-born children, 42; apoplexy of, with venous pulsation, 101; and heart, disease of, 197; gangrene of, in the insane, 795.
- Lupiferum sulphuris, hydriodate of potash in, 628.
- Lymphatics, dilatation of, 969.
- Lynn Self-supporting Dispensary, 629.
- M
- Macartney, Dr., on water-dressing, 450.
- Mackenzie on the Eye, 631.
- Mackenzie, Captain, inquest on, 920.
- Macleod, Roderick, fabrications by, 114.
- Maddock, Mr., on copahal fever, 700.
- Magistrates, medical, letter respecting, 748.
- magnetism, mineral, as a remedial agent, 338, 366; report respecting, 506; trial of, at the Westminster Eye Hospital, 540; Dr. Schmidt on, 593; notice respecting, 633; Mr. Davidson's reply to Dr. Schmidt on, 715; Dr. Ritchie on, 724.
- Manchicheel juice in cancer, 266.
- Manby, Mr., on medical attendance on the poor, 710.
- Manganese, medicinal preparations of, 568; in epist. xis, 568.
- Mart, Dr., on nervous diseases, 112; death of, 112.
- Martinez, duties of, 631.
- Martinez, letters by, on remuneration at surgeons' inquests, 629, 748.
- Martinez, and Paris, Messrs., 546.
- Maxillary, inferior, removal of, 221; superior and malar bones, removal of, 917.
- McCarthy, Dr., on a case frequently simulating hydrophobia, 25; case by, of obstruction of the bowels, 133; of wounded patella, 204.
- McNab's Compendium of the Ligaments, 586.
- Measles following croup, 951.
- Medical degree, Mr. Prater's examination for, 184.
- Medical Gazette, disavowal of editorship of, 727; horror of being suspected of editing, 752.
- Medical students of London, attacks on, 754.
- Medical Reform Essays, 519.
- Medicines, nauseous solid, 271.
- Medicinal plants, localities of, 341.
- Medico-Botanical Society, discussions at, on the death of Mr. G. Burnett, 266; Manchicheel juice in cancer, 266; new catechu, 311; cardamom seeds, 311; castor-oil plant, 341; medicinal plants, localities of, 314; Peruvian bark, 633; meetings of, 945.

THE LANCET.

OL. I.]

LONDON, SATURDAY, SEPTEMBER 26, 1835.

[1835-36.]

PREFACE

TO THE VOLUMES OF THE LANCET FOR 1835-36.

THE act of writing a PREFACE to a book, so often resembles the ceremonial of a first introduction to a new company, that it is generally executed with some degree of awkwardness, and, very frequently, under the pressure of embarrassed feelings. In our own case the plea of novelty, or of a first appearance, cannot be urged in extenuation of an imperfect discharge of our duty. But prefatory introductions to new works are generally compounded of the reasons which have induced the author to publish, and of promises relative to the materials which he will furnish for the amusement or the gratification of his readers. After twelve years of anxious and successful labour in the field of medical reform, it is unnecessary to reintroduce the reasons which first prompted the writer to publish THE LANCET; and, from circumstances and motives equally obvious and conclusive, we will not derogate from the character and influence of this journal, by inviting, through the instrumentality of pledges and promises, a more general attention to the subjects which are usually introduced into its columns. The occurrences of by-gone years must be taken, in both instances, as the best and surest guarantees of what the events of future years will produce. If, after the obstacles which we have successfully encountered and overcome; if, after the monopolies which we have demolished, and the monopolists whom we have made quail; it could be necessary to offer one word in proof of our sincerity and devotedness to the cause which we have so long advocated, why then, indeed, the prospect before us would exhibit a dreary void, unenlivened, uncheered, by a single feeling of inspiring hope. The pioneer in works of reform, labours but with a sorrowing mind when he is not urged onwards by the stimulating confidence of those persons who observe, and who are capable of understanding, the tendency of his actions. When, therefore, the success of THE LANCET, and the wide diffusion of the principles which that journal has advocated in promoting the cause of medical reform, are taken into consideration, it must be recollected that neither of those results would be observable at the present period, had not the great majority of the members of the medical profession contributed, by their powerful support, towards making that journal the great instrument of their liberation from the bondage of the universities, hospitals, and other chartered medical corporations. Here, then, all medical reformers stand on an inviting, an enviable, a commanding position. Although they were perplexed, trammelled, and obstructed

at every step in the commencement of their career, the onward movement of events in twelve brief years has terrified the conceited and titled drones attached to our colleges and hospitals into an acknowledgment of their guilt and impotence, and has converted many of them from being the most insolent of tyrants into the most submissive of hypocrites. It is not in one or two medical establishments only that the changes which have been effected are perceptible. The entire body is convulsed, and in several of the extremities of the hideous monster, MONOPOLY, the agonizing throes which precede dissolution, are at once both seen and felt. We are not advancing towards the goal of improvement by tardy lingering steps, but by a salient movement; and the strength which is daily acquired as the labour advances, gives an assurance, which cannot be shaken by any temporary disaster or check, of an unqualified and permanent success.

What, then, is the ultimate object of the national work in which medical reformers are engaged? Nothing less than the conservation of the public health. To this great end it is sought to bring the whole power and force of the principles of the science of medicine into active operation. Hence it is in the contemplation of what medicine *might* achieve, that we witness, at every step, in our charitable and public institutions, the barriers and drawbacks which have hitherto defrauded the public out of those manifold advantages which it is in the power of the learned and experienced members of the profession to confer. At present the whole system of medical government is sustained on the odious principles of self-election and monopoly. It is a compound of nepotism, knavery, and extortion. The highest posts of honour are occupied for the most part by imbeciles; and men endowed with the highest attainments which can ornament the human mind,—who may have endeavoured to obtain rank in our public institutions through the instrumentality of merit,—unaided by the influence of wealth and family connexions, would engage in a toil which could have no other result than that of bitter disappointment.

As illustrative of the exclusive character of the proceedings in our hospital and other public medical institutions, we cannot call to mind, at this moment, a single instance in which a medical student in this metropolis,—out of all the hundreds and thousands who have attended our schools since this journal was first published,—on whom has been conferred a post of honour and emolument as a just reward for his industry and attainments. This is a frightful fact. It is puerility itself to employ argument in denouncing such a system. In what other quarter do we find its parallel? In what other profession? Certainly not in the Church. Obviously not in the Law, for, in both, men of industry and great mental powers are sure of obtaining preferment. In medicine the highest collegiate title is that of the *doctorate*: yet it has been, and is now, obtainable by a display of *talent*—it is almost a profanation to use the term in this place—which would excite even the derision of the drug-dealers in Rhubarb Hall. Still this distinction may be obtained by *residence*, by *lounging*, and by *money*. The M.D. is then turned adrift upon society—let loose like a newly-weaned, wild, and cast-off monster, to feed and fatten on the vitals of the community.

Why, in every county town with its four and five thousand inhabitants throughout the kingdom, there lived, not ten years back, your puny boy-doctor, a “graduate,” an “university man,” it is true, but who, of hospitals knew only that they existed, and the peculiarities of disease knew nothing. Henceforth these ambitious aspirants, at Jericho till their beards be grown.” The surgeon in general practice, with ten, fifteen, and twenty years experience, is not to be thrust aside by such aspirants for fame. Our medical colleges have been so many medical nuisances, and have tended

every possible way, the advancement of that science which they were instituted to promote and protect. Arouse your energies, then, English surgeons. Continue your exertions in the cause of medical reform, and suffer them not for one instant to relax or abate. It is in consequence of your advocacy and sustenance of the principles which have from time to time been promulgated in the pages of this journal, that so much has been achieved. We can feel no reluctance in taking to ourselves that portion of reward and praise which is our due, for having projected and instituted a free medical press,—for having insisted on and obtained the right to publish lectures which are delivered on public medical foundations,—for having proclaimed and enforced the right to publish the cases which are presented to the view in the wards of our hospitals; but had we not found a spirit of sympathy among the mass of our professional brethren, all our exertions would have proved fruitless, all our anxieties and labours must have been utterly and wholly unproductive. Diffused as are the members of our profession over the entire surface of the country; moving as they are in the first circles of society, what legitimate object is there connected with the science of medicine, which it is not in their power to accomplish? Left free and unshackled by the odious trammels of parliamentary statutes, the science of medicine would have flourished, would have asserted and established its supremacy, amongst a people so thoughtful and reflective as the English. But it is only now fettered by chains which have been rusting and decaying for upwards of three hundred years. The operations of time, however, have at length so weakened these galling and perplexing restraints, that a few more efforts on the part of the oppressed will break them into atoms and cast them aside for ever.

What, then, is wanting in medicine in order to give the best security to the public health, and to clear away all the rubbish, toll bars, and checks, which are still to be found on the road of medical preferment? Of no consequence is it under what names they exist, whether under those of universities, colleges, hospitals, or schools. They must not be allowed to obstruct genius in the pursuit of knowledge and of fame. If these institutions cannot, by a wise and prudent system of legislation be rendered subservient to the exalted objects of medical science, the interests of society demand that they should be diverted to some other purposes, or that they should cease to exist. No point now remains to be elucidated on this subject; it is adequately understood by every tyro in the profession. In the evidence which was taken before the Parliamentary Medical Committee, and a considerable portion of which has lately been published in this journal, it has been shown that the surgeons of England who are engaged in the duties of a general medical practice, were spoken of by some of the self-elected heads of their own College, as a subordinate class of medical society—nay, as men who were aliens to the medical profession. The very by-laws of the College sink them into an inferior position, and attainments superior to those of mere handicraft degrade them beyond the pale of medical advancement. Manual dexterity is placed in the ascendant, while a knowledge of the principles of medical science brings upon its possessor an infliction which approaches in character to the severity of a penal punishment. If the members of the British Colleges of Surgeons could submit tamely and silently to injustice and insult of such a nature as this, they would deserve only the scorn of every enlightened member of the community, instead of that sympathy which is now their reward for the exertions which they have progressively and successfully made against their oppressors. Never was there a time more favourable than the present for making those exertions. Never was the legislature more sincerely disposed to listen to and concede the just claims of the professors of medicine. But it would be folly to rely on a friendly disposition when positive acts are required for our

benefit. Those surgeons, therefore, of the United Empire, who are solicitous that genius should have a clear field for exertion,—that merit should receive its due reward,—that monopolies in medical practice should be destroyed,—that the system of teaching in our medical schools should be placed on a new footing,—that the offices in our hospitals should no longer be obtained by family interest or intrigue,—that secret remedies should no longer be tolerated under the sanction of a government stamp,—that uniformity of title in the ranks of the profession should be made to depend on uniformity of attainments in medicine,—such advocates of reform will continue to bestir themselves, and devote their faculties to promote the success of the cause which they have so long supported. The application of excited energies, however, can be of little avail, if the power so exercised be not properly directed. Hitherto there certainly has been no misapplication of that moral and intellectual influence which the members of the medical profession are able to direct against their enemies and persecutors. All our grievances are traceable to the defective state of the law. Towards the Legislature, therefore, every movement tending to promote an improvement of that law should be employed; and, as there is a perfect concordance of opinion amongst British medical practitioners relative to the extent and character of the abuses which are connected with the science and practice of medicine, there will be little difficulty in establishing a complete unity of action towards effecting their removal. If it were not for the obstacles which exist in the form of Charters and Acts of Parliament, medical practitioners might, by a judicious combination of their abilities and numbers, carry out their views into a well organized system of government. But the strong arm of the law now interposes its power, and forbids any final adjustment of the question, without the intervention of the Legislature. As this is a fact which remains undisputed and is indisputable, there is no surgeon in the empire who has devoted the smallest portion of his time to a consideration of the subject of medical grievances, who will not freely and candidly admit that it is to the Legislature, and to the Legislature alone, that application must be made for an instrument which will be adequate to the demolition of our incorporated monopolies.

In acknowledging, also, the supremacy of the Parliament in this respect, it is exalting to observe the kindly sympathy which the complaints of the profession have already excited in both Houses of the Legislature. If a reference be made to the debates in the Houses of Commons and Lords on the passing of the Apothecaries Act in 1815, and to the discussion in the House of Commons on the introduction and rejection of the Surgeons Bill in 1816, it will be perceived that a most extraordinary revolution has occurred amongst our senators, regarding the claims which medical practitioners have set forth for the purpose of showing that they are entitled to protection from Parliament. But in 1815 the question of MEDICAL REFORM was not understood either in or out of Parliament. It had been, then, only partially discussed. A few petty grievances had been considered, and some imperfect remedies had been suggested, but no comprehensive system of medical government had—so far as we have been enabled to ascertain, from a careful examination of the writings of that period—engaged the attention, or occupied the minds, of our medical regenerators. During the last twelve years, however, the subject has been unceasingly discussed in all its elementary branches; and we verily believe that the surgeon's apprentice of two years' standing, in 1835, understands more of the question, and could argue it more effectually in writing and in conversation, than could any six members who belonged to the House of Commons in 1815. It is not possible to feel the feeling of encouragement which this rapid advancement has afforded, without energy and exertion!

In admitting, therefore, the supremacy of the Legislature, let us not

of what is our duty towards that depository of the will of the nation. If any individual feel disposed to condemn the Parliament for its conduct in 1815, he is bound, on every principle of justice and sound policy, to use his own individual efforts towards rendering the members of the present Legislature amenable to public opinion for any misconduct in framing and passing crude and incompetent laws for medical government. It is our duty, as well as our interest, to afford to them full and adequate instruction relative to the extent and enormity of medical abuses.

But it may be said that a Committee of the House of Commons, headed by an able and indefatigable chairman, has been appointed to inquire into the state of medical law and practice, that witnesses have been examined, and that evidence has been taken, and much of it printed. Hence it may be inferred, that with such materials at their command, the whole subject of medical government must be well understood by the members of the House of Commons; whereas it is very probable that not more than six members of the medical Committee understand any one portion of the question thoroughly; and that the Chairman is the only member of that Committee whose judgment on the subject of medical policy has been matured and confirmed by a patient, unprejudiced, and philosophic investigation of the abuses connected with the existing system, and who is fully sensible of the principles on which a strictly new system should be established. If the members of the House of Commons could find time to peruse, with the requisite attention, evidence taken before Committees, nothing more would be required to enable them to understand the various questions brought before them. But the reports of the House are so numerous and voluminous, and embrace such a multiplicity of national affairs, that it is not possible for any man, whatever may be his industry, the strength and accuracy of his memory, or the vigour and capacity of his mind, to analyse a twentieth part of the sessional reports which are placed on the table of his study. This deficiency extends, in some measure, to documents connected with every department of the state. There are, possibly, a few men in each House of Parliament who are capable of discussing with accuracy several prominent important features of every great question; but it seldom happens that more than two, or three members, especially if the subject be new to the House, who take a view of the whole question, and understand it thoroughly. In law reforms, in church reforms, in municipal reforms, in matters of international commerce, the accuracy of this statement is sustained by a vast mass of facts. Whenever, therefore, it is sought, in either House of Parliament, to institute a new law, the parties interested in the success of the measure invariably furnish the members of the senate with a "digest" of their "reasons" for urging institution, and an abstract of the principles on which the new enactment is to be founded. Various means are adopted for this purpose. Petitions are placed in the hands of the members. Printed explanations of the arguments which can be adduced in favour of a particular bill are industriously insinuated into the hands of the members in the lobby and passages of both Houses. The agents for new bills, and the friends and supporters of those measures, visit many of the members personally, and explain orally the objects which they have in view; and, when the claims of the parties are well founded,—are sustained by the principles of justice and of reason, their efforts, in nineteen cases out of twenty, are ultimately rewarded with success.

In calling on British surgeons who are engaged in the practice of medicine to adopt a new course of procedure, we are only, in fact, entreating them to conform to a course which they have already employed so energetically, and with such manifest advantage, in furtherance of the cause of medical reform. Of all the modes of attack which can be levelled with the best prospect of success against ignorance and pre-

PREFACE.—MEDICAL REFORM.

judice, there is none equal to the enforcement of truth in personal conversation. Doubts are dissipated as they arise; questions are instantly answered; objections are suddenly removed. The organs of speech are instruments of infinite power when their movements are directed by a judicious and well-fortified mind. Already have the members of the profession proceeded in the work of senatorial instruction most industriously and impressively. We implore of them not to relax in their exertions. The fruit of their labours is already apparent in the desire which the House of Commons has recently manifested to render justice to the members of the medical profession. The science of medicine itself is spoken of with admiration in that assembly, and the claims of medical practitioners are treated with marked attention. The tone of the Commons in the instance is not more striking than it is extraordinary, considering the temper and ignorance of that body on medical subjects, so lately as in 1815. The alteration can neither be explained nor understood, except by making an unqualified acknowledgment of the value of the individual exertions of the members of the profession amongst members of the Legislature residing in their respective localities. In earnestly entreating that those exertions may be unremittingly continued until the next session of Parliament,—in imploring our professional brethren to embrace every opportunity which may be made instrumental in acquainting members of both Houses of the Legislature not only with the extent and character of medical abuses, but also with the principles on which a new law should be instituted for establishing ONE UNIFORM SYSTEM OF MEDICAL GOVERNMENT, executed TRIPARTITELY, in the three great divisions of the empire, we are, in reality (and we write under a conviction which is founded on personal observation), beseeching them to take that course which will lead to the speediest and happiest termination of their labours; and while the value of the disinterested and patriotic efforts made by British surgeons in the cause of humanity and justice, will be gratefully acknowledged by an intelligent community, the splendid results of those efforts will be solemnly proclaimed to the world, in an ACT of the Imperial Parliament.

LIST OF THE SCHOOLS OF MEDICINE

IN LONDON,

OPEN TO STUDENTS IN THE SESSION 1835-36.

the districts of the metropolis in which medical schools are situated, may be rated, according to the situation of the schools, into the following divisions :—
1. containing the *London Hospital*, situated at the eastern extremity of London, in Whitechapel-road.

2. containing *Guy's* and *St. Thomas's Hospitals*, situated in Southwark, near the end of London Bridge.

3. containing *St. Bartholomew's Hospital*, situated in Smithfield.

4. containing the *North London Hospital* and the *Middlesex Hospital*, near Tottenham Court Road.

5. containing the *Westminster Hospital*, situated at the back of Westminster Abbey—
which division, if not in the previous list, the *Charing-Cross Hospital* may be added, when it is "recognised" by the local boards; an event which circumstances will, most probably before the expiration of another year, render unnecessary to establish as an office for the sale of tickets to students; and, finally,
6. containing *St. George's Hospital*, situated at Hyde Park Corner.

In each of these institutions there is now held an association of gentlemen who deliver courses of lectures on those subjects here named in the "Regulations" of the Apothecaries' Company and the College of Physicians, and in their neighbourhood there are several other similar courses attended, if the student prefers expending his money at the latter instead of at the former.

Institute any comparison between these various establishments, for the difficulty of selection amongst them, on the score of superiority of advantages and instruction, becomes every year more difficult, (with one or two exceptions, which have already been indicated in the pages of this journal,) we proceed at once to lay before our readers a digest of the advertisements issued from them, in the order enumerated in the preceding list of the hospitals. We may first premise, however, that on comparing the present arrangements of the schools with those of last year, the change of lecturers, and the rising and sinking of schools, are not less numerous than they were observed to be at the commencement of the last session, as compared with the arrangements of the session before that. How, in fact, the lecturers can, with any approach to gravity of countenance, in the face of these incessant variations, allow themselves to offer to students the option of "perpetual" attendance to their courses of lectures, we know not. The word "perpetual," however, is to be found in almost every prospectus, and we may here observe that in the lists of fees in the subjoined tables, the second sum is the fee required for entrance under that head. The first sum is the fee named for single courses, either of three or six months duration. Reserving, then, such observations as we may be disposed to offer to students on this occasion until the list of schools is concluded, we begin at the east end of the metropolis, and insert first an account of the

LONDON HOSPITAL SCHOOL AND PRACTICE.

Subjects.	Lecturers.	Days and Hours of Lecturing.	Fees.	
Medicine.	Dr. Billing and Dr. Davies.	Tues. Thurs. & Fri. at 3½ p.m.	£ 4	8 7 7
Materia Medica.	Dr. Cobb.	Wed. and Fri. at 9 a.m.	3 3	& 4 4
Midwifery.	Dr. F. Ramsbotham.	Tues. Thurs. & Sat. at 10.	3 3	& 7 7
Chemistry.	Mr. Pereira.	Mon. Wed. and Fri. at 10 a.m.	4 4	& 8 8
Medical Jurisprudence.	Dr. Cobb, Dr. F. H. Ramsbotham, and Mr. Pereira.	Saturday, at 3½ p.m.	3 3	& 4 4
Anatomy, Phys. & Operations of Surgery.	Messrs. Luke, Hamilton, & Adams.	Daily, at 2½ p.m.	5 5	& 10 10
Anatomy, with Dissect. &c.	Messrs. Hamilton & Adams.	Daily, from 11 till 4.	3 3	& 10 10
Surgery.	Mr. John Scott.	Mon. Wed. Fri. at 7 p.m.	3 3	& 5 5
Botany.	Messrs. Pereira and Quekett.	No days named.	3 3	& 1 4
Compar. Anat.	Mr. W. J. Little.	In the Spring.		
Morbid Anat.	Mr. T. B. Curling.			

The *Physicians* of the hospital are, Dr. Frampton, Dr. Billing, and Dr. Gordon. 20 guineas; for six months as dressing pupil, 20 guineas; library fee, 1 guinea.

The *Surgeons* are, Mr. Andrews, Mr. John Scott, and Mr. Luke.

The fee for admittance to the *Physicians' practice* is, for twelve months, 16 guineas; for perpetual attendance, 20 guineas; the apothecaries' fee, 1 guinea.

The fee for attendance on the *Surgeons' practice* is, for twelve months, 20 guineas; for twelve months as dressing pupil, 30

Lectures commence October 1st,* at hall-part 2. General fee for attendance upon all the above Lectures, qualifying for Royal College of Surgeons and Apothecaries' Hall, 50l.

Promises.—1. Clinical Lectures by the Physicians and Surgeons. Dr. Billing is one of those gentlemen who strictly abides by his share in the promise here given. 2. A Spring course of Comparative Anatomy, by Mr. W. J. Little.

ST. THOMAS'S HOSPITAL SCHOOL AND PRACTICE.

Subjects.	Lecturers.	Days and Hours of Lecturing.	Fees.	
Medicine.	Dr. Williams.	Mon. Wed. and Fri. at 10 a.m.	£ 3	8 6 6
Mat. Medica.	Dr. Burton.	Mon. Wed. & Fri. at 1 p.m.	0 0	— 1 4
Midwifery.	Dr. Rigby.	Tues. Thurs. and Sat. at 4 p.m.	3 3	& 6 6
Chemistry.	Mr. R. Phillips.	Tues. Thurs. and Sat. at 10 a.m.	4 4	& 6 6
Med. Juris.	Dr. Lister and Mr. R. Phillips.	Tues. and Fri. at 12.	3 3	& 4 4
Anatomy, &c. and Demonstrations.	Messrs. Tyrrell, Mackenrodo, & Solly, & Messrs. B. Travers, jun., & Mr. Clarke.	Daily at 2½ p.m., & 11 a.m.	8 8	& 15 15
Surgery.	Messrs. Travers and Tyrrell.	Mon. and Fri. at 8 a.m., and Wed. at 7 a.m.		
Botany.	Mr. J. Hayes.	Not till April.		

* In every school the lecturing commences on this day.

The fees for attendance on the medical practice of the hospital are, physicians' pupil, two years, 24*l.* 3*s.*; one year, 15*l.* 15*s.*

The physicians make their visits daily, at one o'clock; Dr. Williams on Mondays and Thursdays; Dr. Roots on Tuesdays and Fridays; Dr. Barton on Wednesdays and Saturdays; Dr. Lister sees the out-patients on Thursdays and Saturdays at eleven.

The fees for attendance on the *Surgical* practice are, Dresser, one year, 51*l.* 2*s.*; six months, 32*l.* 12*s.*; Surgeons' pupil, one year, 26*l.* 6*s.*; six months, 20*l.*; a second entry, if within two months, 6*l.* 12*s.*

The Surgeons make their visits daily, viz., Mr. Travers on Mondays and Thursdays at one o'clock; Mr. Green on Tuesdays and Fridays at one o'clock; Mr. Tyrrell on Wednesdays and Saturdays at half-past one o'clock; Mr. South sees the out-patients on Mondays and Wednesdays at eleven o'clock; on Fridays operations are performed.

Promises.—1. Anatomical Examinations, by the Lecturers and Demonstrators, twice a week.—2. Attendance in the Dissecting-room by the Lecturers from twelve o'clock, and by the Demonstrators from ten o'clock, until half-past two, daily.—3. Lectures on Morbid Anatomy, by Dr. Barker.—4. Clinical Lectures will be delivered to the Physicians' pupils, by Dr. Williams, Dr. Roots, and Dr. Burton, and to the Dressers and Surgeons' pupils, by Mr. Travers, Mr. Green, and Mr. Tyrrell.—5. Pupils entering to the Surgical practice of St. Thomas's Hospital, are allowed to attend that of Guy's.—6. Post-mortem Examinations at one o'clock, by Dr. Barker.—7. A Distribution of Prizes will take place in May.—8. The use of the Library and Reading Room allowed, so long as gentlemen continue attending the practice or lectures.

GUY'S HOSPITAL SCHOOL AND PRACTICE.

Subjects.	Lecturers.	Days and Hours of Lecturing.	Fees.	
			£ s.	£ s.
Medicine.	Drs. Bright and Addison.	Mon. Wed. and Fri. at 3½ p.m.	4 4	& 8 8
Mat. Medica.	Dr. Addison.	Tues. Thurs. and Sat. at 3½ p.m.	3 3	& 4 4
Midwifery.	Dr. Ashwell.	Daily at 8½ a.m.	3 3	& 10 10
Chemistry.	Messrs. Aikin and Taylor.	Tues. Thurs. and Sat. at 10 a.m.	4 4	& 8 8
Med. Juris.	Mr. A. Taylor.	Mon. and Fri. at 10 a.m.	3 3	& 4 4
Anatomy, &c.	Messrs. Cooper and Cook.	Daily at 2 p.m. & 10 a.m.	8 8	& 21 0
Surgery.	Messrs. Key and Morgan.	Tues. Thurs. and Fri. at 8 p.m.	3 3	& 5 5
Botany.	Mr. C. Johnson.	Mon. Tues. Thurs. Fri. at 4½ p.m.	2 2	
Morbid Anat.	Dr. Hodgkin.	Tues. Thurs. Fri. at 6½ p.m.	2 2	
Compar. Anat.	Mr. T. Bell.	Mon. and Wed. 47 p.m.	2 2	

The physicians of the Hospital are, Drs. Cholmeley, Bright, and Back. The surgeons are Messrs. Key, Morgan, and B. Cooper.

Hospital Practice.—Physicians' pupils, perpetual, 24*l.* 4*s.*; one year, 15*l.* 15*s.*

Surgeons' dresser, one year, 51*l.* 2*s.*; six months, 32*l.* 12*s.*

Surgeons' pupil, one year, 26*l.* 6*s.*; six months, 20*l.*; a second entry within two months, 6*l.* 12*s.*

Promises.—1. Clinical lectures, by the

physicians and by Dr. Ashwell, whose pupils are allowed to attend the Hospital Lying-in Charity (?)—2. Lectures on the teeth, by Mr. T. Bell.—3. Clinical lectures and instructions by the surgeons.—4. Sir Astley Cooper (will attend as) consulting surgeon.—5. The surgical pupils of Guy's may attend that of St. Thomas's.—6. The use of the library, reading-room, and botanic garden.—7. The time of the lectures not to interfere with that of the practice.

THEATRE OF ANATOMY AND MEDICINE

WEEB STREET, MAZE POND, BOROUGH.

Subjects.	Lecturers.	Days and Hours of Lecturing.	Fees.			
Medicine.	Dr. Whiting.	Mon. Wed. and Fri. at 4 p.m.	£	s.	£	s.
Mat. Medica.	Dr. Whiting and Mr. Everitt.	Tues. Thurs. and Sat. at 10 a.m.	4	4	&	6 6
Midwifery.	Dr. F. H. Ramsbotham.	Tues. Thurs. and Sat. at 7 p.m.	3	3	&	4 4
Chemistry.	Mr. Cooper.	Mon. Wed. and Fri. at 10 a.m.	3	3	&	6 6
Med. Juris.	Dr. S. Smith & Mr. Cooper.	Tues. and Thurs. at 4 p.m.	4	4	&	6 6
Anatomy, Physiology, and Demonstrations.	Messrs. Grainger, Pilcher, Millard, and E. Barron.	Daily, at 2½ p.m. & at 11½ a.m.	3	3	&	5 5
Surgery.	Messrs. Grainger and Pilcher.	Mon. Wed. and Fri. at 6 p.m.	8	8	&	15 15
Botany.	Dr. R. Dickson.	Daily 49 a.m.	3	3	&	5 5
			3	3	&	4 4

Mr. Grainger will deliver the introductory lecture at 11½ a.m., on Thursday, Oct. 1.

Promises.—1. Official superintendence in the dissecting-room.—2. The museum open to students.—3. Gentlemen entering to the

course on medical jurisprudence will have the privilege of attending gratuitously the practice of the London Fever Hospital. Periodical examinations of the students.

ST. BARTHOLOMEW'S HOSPITAL SCHOOL AND PRACTICE.

Subjects.	Lecturers.	Days and Hours of Lecturing.	Fees.			
Medicine.	Dr. Hue.	Tues. Thurs. and Sat. at 10 a.m.	£	s.	£	s.
Mat. Medica.	Dr. Roupell.	Mon. Wed. and Fri. at 3½ p.m.	1	4	&	6 6
Midwifery.	Dr. Hugh Ley.	Tues. Thurs. and Sat. at 7 a.m.	3	3	&	4 4
Chemistry.	Dr. Hue.	Mon. Wed. and Fri. at 10 a.m.	3	3	&	7 7
Med. Juris.	Dr. Burrows.	Wed. and Fri. at 4 p.m.	4	4	&	8 8
Anatomy, Phys., and Demons.	Messrs. Stanley, Wornald, & McWhinnie.	Daily, at 9 a.m. and 2½ p.m.	3	3	&	4 4
Surgery.	Mr. Lawrence.	Mon. Wed. and Fri. at 7 p.m.	8	8	&	21 0
Botany.	Dr. F. J. Farre.	Mon. Tues. Thurs. Fri. and Sat. at 11½ a.m.	5	5	&	8 8
Compar. Anat.	Dr. A. Farre.	Tues. Fri. at 2½ p.m.	3	3	&	4 4
			1	1	&	2 2

The hospital officers are, Drs. Hue, Latham, and Roupell, physicians; and Messrs. Vincent, Lawrence, and Earle, surgeons.

Dr. Hue attends at 11½ a.m. on Mondays and Saturdays, at 11 to see out-patients, and 12½ to see in-patients on Thursdays. Dr.

Latham on Mondays and Tuesdays at 1 and at 8 a.m. on Fridays. Dr. Roupell

Mr. Vincent attend at 11½ a.m. on Thursdays, and Saturdays at 12½ on Mondays, Wednesdays, and Fridays. Mr. Earle at 12½ on Tuesdays.

lays and Saturdays. Dr. G. Burrows at 11 in the out-patients' room, except on Thursdays.

The fees for attendance are,—on the Medical Practice for an unlimited period, thirty guineas; for eighteen months, fifteen guineas; for nine months, twelve guineas.

On the Surgical Practice, for twelve months (or perpetual), twenty-five guineas; for six months, eighteen guineas.

As dresser, for twelve months, fifty guineas; for six months, thirty-six guineas.

Promises.—These are so numerous that we should advise students who enter here to provide themselves with, and take care of, a *pamphlet* to be had at the hospital, in which the whole routine of the lectures and practice is advertised.

ALDERSGATE SCHOOL OF MEDICINE,

(Near St. Bartholomew's Hospital.)

Subjects.	Lecturers.	Days and Hours of Lecturing.	Fees.	
Medicine.	Dr. Marshall Hall.	Mon. Wed. and Fri. at 8½ p.m.	£ s.	£ s.

Botany.	Messrs. Pereira and Quekett.	(No time named.)	3 3	& 4 4
Comp. Anat.	Dr. R. E. Grant.	Tues. and Thurs. at 6 p.m.	12 lect.	1 1

Promises.—1. Extra lectures on Medical by Dr. Birkbeck.—2. Attendance on labours and Morbid Anatomy by Dr. Hall.—3. Gratuities to qualified midwifery pupils.—4. Botanical excursions in the summer.

UNIVERSITY OF LONDON, AND NORTH LONDON HOSPITAL.

Subjects.	Lecturers.	Days and Hours of Lecturing.	Fees.	
Medicine.	Dr. Elliottson.	Daily at 8.	5 0	& 8 0
Mat. Medica.	Dr. A. T. Thomson.	Daily except Sat. at 3 p.m.	6 0	& 9 0
Midwifery.	Dr. D. D. Davis.	Mon. Wed. Fri. at 9 a.m.	5 0	& 7 0
Chemistry.	Dr. Turner.	Daily at 10 a.m.	7 0	& 10 0
Med. Juris.	Dr. A. T. Thomson.	Tues. and Sat. at 4½ p.m.	3 0	
Anatomy, &c.	Dr. Quain and Mr. R. Quain.	Daily except Sat. at 2 p.m. and daily dissections.	12 0	& 18 0
Surgery.	Mr. S. Cooper.	Mon. Wed. and Fri. at 7.	4 10	& 6 0
Botany.	Dr. Lindley.	Tues. Thurs. and Sat. at 9 a.m.	3 0	& 6 0
	Dr. Carswell.	Mon. Wed. and Fri. at 10.	3 0	
	Dr. Grant.	Daily, except Thurs. Sat., at 3.	3 0	
Veterinary Med.	Mr. Youatt.	To begin Nov. 1st.	5 0	& 7 0

The Physicians of the Hospital are, Drs. Elliotson, Thomson, and Carswell; the Surgeons are, Messrs. S. Cooper, R. Liston, and R. Quain. Dr. Davis holds the office of Obstetrical Physician.

Students are admitted to attend the Practice and Clinical Lectures on the following terms:—

For perpetual admission to the Medical and Surgical Practice, 26*l.* 5*s.*

For attendance during one year upon the Physicians' and Surgeons' Practice, 21*l.*

For attendance during one year upon the Physicians' or Surgeons' Practice separately, 15*l.* 15*s.*

For attendance during six months upon the Physicians' and Surgeons' Practice, 15*l.* 15*s.*

For attendance during six months upon the Physicians' or Surgeons' Practice separately, 10*l.* 10*s.*

(Note.) Their proportion of these fees has been relinquished by the Physicians and Surgeons of the Hospital, and is devoted to the maintenance of the establishment.

Every student pays, in addition to these fees, 10*s.* to the Apothecary, and 5*s.* to the Secretary.

House Surgeons, Physicians' Clerks, and Surgeons' Dressers, are selected from the Students without additional payments, preference being given to those who, with equal moral character, have obtained the highest honours in the medical classes of the University.

The Surgeons' visits are made daily from 12 to 1, the Physicians' daily from 1 to 2 o'clock.

Medical and Surgical Clinical Lectures are given several times a week.

Dr. Davis, Dr. Carswell, and Mr. Quain, see out-patients daily in the morning.

This Hospital is rendered by its arrangements and constitution by far the most advantageous in the metropolis for the attendance of students, and we advise all those students with whom circumstances render the choice of a locality subservient to their desire for professional advantages, to examine attentively its claims as a place of instruction. As small pamphlets on the arrangements of the Hospital and the University may be readily obtained at either institution, we shall not further occupy space with regard to them here.

MIDDLESEX HOSPITAL SCHOOL OF MEDICINE.

Subjects.	Lecturers.	Days and Hours of Lecturing.	Fees.			
Medicine.	Dr. Copland.	Mon. Tues. Thurs. Fri. at 3 p.m.	£	s.	£	s.
Mat. Medica.	Dr. Macreight.	Tues. Thurs. Sat. at 9 a.m.	3	3	8	6
Midwifery.	Mr. Sweatman.	Tues. Thurs. Sat. at 10 p.m.	3	3	8	5
Chemistry.	Mr. Everitt.	Mon. Wed. Fri. at 10 a.m.	3	3	8	6
Med. Jurisprud.	Dr. Leighton.	Wed. Sat. at 3 p.m.	3	3	8	4
Anatomy, Phys., with Demon- strations.	Sir C. Bell, Mr. Tu- son, and Mr. Shaw.	Daily at 11 a.m. and 2 p.m.	6	6	8	16
Surgery.	Mr. Arnott.	Mon. Wed. Fri. at 9 a.m.	3	3	8	5
Botany.		(During the summer.)	2	2	8	3

The Physicians of the Hospital are, Drs. Hawkins, Watson, and Wilson. The Surgeons are, Sir C. Bell, Mr. Mayo, and Mr. Arnott.

The terms of attendance on the medical practice are, during three months, six guineas; six months, ten guineas; nine months, twelve guineas; twelve months, fifteen guineas; unlimited attendance, twenty-one guineas. Apothecary's fee, one guinea.

The terms of admission of surgeons' dressers and pupils are, dresser for twelve months, 31*l.* 10*s.*; for six months, 21*l.* Pupil, for twelve months, 21*l.*; for six months, 15*l.* 15*s.*; for three months, 10*l.* 10*s.*

From the dressers the house-surgeon is elected, agreeably to his date of entrance. A pupil may be allowed three months' dressing during the time of his pupillage, by paying 10*l.* 10*s.* extra.

Promises.—Clinical lectures from all the medical and surgical officers of the hospital.

HUNTERIAN THEATRE OF ANATOMY.

GREAT WINDMILL STREET, LONDON.

Lectures on *Anatomy, Physiology, Pathology, and Surgery*, by Mr. John Smith, and Mr. Richard Buxie.

mening on the 1st of October. A Lecture daily, at half past two o'clock. Dissections and Demonstrations from the 8th of October daily. Terms of the Lectures:—One course of both, 6*l.* 6*s.*; perpetual to both 12*l.* 12*s.* The Lectures and Dissecting-rooms will be open free of expense, to the perpetual pupils of the former school at this Theatre, and to the perpetual pupils of the late Joshua Brookes.

MEDICAL SCHOOL, WESTMINSTER DISPENSARY.

Midwifery.	Dr. Ryan.	Tues. Thurs. and Sat. at 11 a.m.	One course on Mat. Med., 3 <i>l.</i> 3 <i>s.</i> ; one on Chemistry, 5 <i>l.</i> 5 <i>s.</i> ; one on Botany, 5 <i>l.</i> 5 <i>s.</i> ; one on Botany, 2 <i>l.</i> 2 <i>s.</i> ; perpetual to all three, 10 <i>l.</i> 10 <i>s.</i>
Chemistry.	Dr. Epps.	Tues. Thurs. and Sat. at 9 a.m.	
Med. Jurisprud.	Dr. Ryan.	Fri. at 11 a.m.	
Anat. Phys. Demons. & Surg.	Mr. Dermott.	Daily at 10 a.m., and 3 p.m.	Anat. Phy. Demons. and Surg.—Single course, 5 <i>l.</i> 5 <i>s.</i> ; perpetual to all, 7 <i>l.</i> 7 <i>s.</i>
Surgery.	Mr. Dermott.	Daily at 3½ p.m.	
Botany.	Dr. Epps.	In the Summer.	

BLENDHEIM-STREET SCHOOL OF MEDICINE.

Founded by the late Joshua Brookes.

As we have received no prospectus of this school, we are compelled to insert the only account we possess of it, as it is contained in an advertisement inserted on the cover of the journal.

The Winter Courses commence October 1st.

Anatomy, Physiology, and Morbid Anatomy, by Mr. King, assisted by Mr. Savage.

Demonstrations and Dissections, by Mr. King, Mr. Thurnam, and Mr. Evans.

Medicine, by Dr. Litchfield (whose Pupils may attend his Practice at the Westminster Dispensary).

Surgery and Surgical Operations, by Mr. King.

Chemistry and Pharmacy, by Dr. R. D. Thompson.

Materia Medica and Botany, by Dr. Steggall.

Midwifery, and the Diseases of Women and Children, by Dr. Richmond.

Medical Jurisprudence, by Dr. Litchfield and W. Theobald, Esq., Barrister-at-Law.

KING'S COLLEGE MEDICAL SCHOOL.

Subjects.	Lecturers.	Days and Hours of Lecturing.	Fees.	
Medicine.	Dr. F. Hawkins.	Mon. Wed. and Fri. at 9 a.m.	£ s.	£ s.
Mat. Medica.	Dr. B. Hawkins.	Mon. Wed. and Fri. at 11 a.m.	3 3	& 6 6
Midwifery.	Dr. R. Ferguson.	Tues. Thurs. and Sat. at 11 a.m.	3 3	& 6 6
Chemistry.	Mr. J. F. Daniell.	Mon. Wed. and Fri. at 3 p.m.	4 4	& 10 10
Med. Juris.	Dr. Watson.	Tues. and Thurs. at 3 p.m.	3 3	& 4 4
	Messrs. Mayo and Partridge.	Daily, except Wed., at 2 p.m., and daily at 10½ a.m.	8 8	& 18 18
Surgery.	Mr. J. R. Green.	Mon. Wed. Fri. at 8 a.m.	4 4	& 6 6
Botany.	Mr.	Tues. Thurs. Sat. at 9 a.m.	4 4	& 6 6

8 CHARING-CROSS, WESTMINSTER, AND ST. GEORGE'S HOSPITALS.

Near King's College is the Charing-Cross Hospital, in which there are four physicians:— Drs. Shearman, Golding, Sigmond, and Chowne; and two surgeons, Messrs. Pettigrew and Howship; and their attendance takes place daily at twelve. The charge to medical students for permission to walk through the wards daily at that hour, are, to the medical practice for nine months, 10*l*. 10*s*; for the full period required by the existing regulations, 15*l*. 13*s*. and 21*l*. Surgical, for six months, 12*l*. 12*s*. Clinical lectures are promised by the physicians and surgeons of the hospital. The question as to the "recognition" of the hospital at the College of Surgeons and Apothecaries' Hall must be answered at those institutions respectively. (See page 11.)

A pamphlet full of arrangements and promises may be obtained at the College.

WESTMINSTER SCHOOL OF MEDICINE.

Subjects.	Lecturers.	Days and Hours of Lectures.	Fees.			
Medicine.	Dr. Burne.	Mon. Wed. Fri. at 9 a.m.	5	5	&	6 6
Mat. Medica.	Dr. Weatherhead.	Mon. Wed. Fri. at 11 a.m.	5	5	&	6 6
Midwifery.	Messrs. North and Griffith.	Tues. Thurs. Sat. at 11 a.m.	5	5	&	6 6
Chemistry.	Mr. Crump.	Tues. Thurs. Sat. at 9 a.m.	5	5	&	6 6
Medic. Jurisprud.	Dr. Graham.	Mon. Thurs. at 10 a.m.	3	3	&	4 4
Anat. and Demon.	Dr. Todd and Messrs. Malyn & Hancock.	Daily lecture at 2½ p.m., and Demons. daily, except Mon., at 10 a.m.	12	12	&	16 16
Surgery.	Mr. Guthrie and Mr. Thompson.	Mon. Tues. and Wed. at 5 p.m.	5	5	&	6 6
Botany.	Mr. D. O. Edwards.	In the summer.	2	2		
Compar. Anat.	Messrs. Dobson and Rush.	Mon. Wed. Fri. at 7 p.m.	2	2		

There is a newly-built hospital near this school, but up to the hour of our writing the conductors were not prepared to state the terms of attendance on its practice. It is probable, therefore, that no students are expected to enter to the practice. Particulars, however, may, possibly, be ready for delivery by the 1st of October to inquiring students. The promises in the prospectus of the school are very similar to those of other medical schools *extra muros*.

SCHOOL OF ANATOMY AND MEDICINE ADJOINING ST. GEORGE'S HOSPITAL.

Subjects.	Lecturers.	Days and Hours of Lecturing.	Fees.			
Medicine.	Drs. Stevens & Wilson.	Mon. Wed. and Fri. at 6 p.m.	4	4		
Mat. Med.	Dr. Wood and Mr. Ansell.	Mon. Wed. and Fri. at 11½ a.m.	3	3	&	5 5
Midwifery.	Mr. Stone and Dr. Davies.	Mon. Wed. and Fri. at 9 a.m.	3	3	&	5 5
Chemistry.	(At the Royal Institution.)	Tues. Thurs. and Sat. at 9 a.m.	3	3	&	5 5
Med. Juris.	Messrs. Broughton and Wilcox.	Tues. and Thurs. at 6 p.m.	3	3	&	4 4
Anat. & Demonstrations.	Dr. Wilson & Messrs. Lane & Harrison.	Daily, 10½ a.m. & 2½ p.m.	6	6	&	16 16
Surgery.	Messrs. Liston and Walker.	Mon. Wed. and Fri. at 7 p.m.	3	3	&	5 5
Botany.	Mr. Hayes.	Tues. Thurs. and Sat. at 11½ a.m.	3	3	&	4 4

ST. GEORGE'S.—PRIVATE LECTURERS.

Two of the lecturers at this school (Dr. Wilson and Mr. Walker) are medical officers of St. George's Hospital, the terms of attendance at which are stated under the head below. The school has been newly arranged, and is now rendered complete in every department of "regulation" lecturing. Between entrance to the lectures at this school, and entrance to the lectures at the hospital, no student ought to hesitate for one moment. Let them enter to the school.

THEATRE OF ANATOMY, KINNERTON-STREET,

WILTON PLACE, ADJOINING ST. GEORGE'S
HOSPITAL.

A Course of Lectures on *Anatomy, Physiology, and Surgical Anatomy*, will be delivered at this School, by Mr. Tatum, and Mr. H. J. Johnson. A Lecture daily at 2½ p.m., commencing on the 1st of October, and a Course of *Demonstrations of Practical Anatomy* will be delivered by Mr. H. J. Johnson, and Mr. H. C. Johnson. A Demonstration daily, at 10½ a.m., commencing on the 10th of October. One course of both, 12*l.* 12*s.*; perpetual to both, 16*l.* 16*s.*

ST. GEORGE'S HOSPITAL SCHOOL AND PRACTICE.

Subjects.	Lecturers.	Days and Hours of Lecturing.	Fees.	
Medicine.	Drs. Macleod and Seymour.	Mon. Wed. and Fri. at 11½ a.m.	£ 3 3	£ 6 6
Mat. Medica.	Drs. Seymour and Macleod.	Tues. Thurs. and Sat. at 11½ a.m.	£ 3 3	£ 6 6
Midwifery.	Dr. Robert Lee.	Mon. Wed. and Fri. at 9 a.m.	£ 3 3	£ 5 5
Chemistry.	None given.			
Med. Juris.	Dr. Hope.	Mon. Thurs. and Fri. at 4 p.m.	£ 3 3	£ 4 4
Anatomy.	None given.			
Surgery.	Mr. C. Hawkins and Mr. G. Babington.	Mon. Wed. Fri. at 8 p.m.	£ 3 3	£ 5 5
Botany.	Dr. Dickson.	Daily, except Saturday, at 14 p.m.	£ 3 3	£ 4 4

Medical and Surgical Practice of the Hospital.—Physicians.—Drs. Chambers, Seymour, Wilson, and Macleod.—Assistant Physician: Dr. Hope. Attendance on the practice of the physicians for nine months, twelve guineas; for one year, sixteen guineas; perpetual pupils, twenty-four guineas. Surgeons: Mr. Keate, Sir B. Brodie, Mr. Hawkins, and Mr. Babington. Assistant Surgeons: Mr. Walker and Mr. Cutler. Attendance on the Practice of Surgeons for

six months, fifteen guineas; for one year, twenty guineas; perpetual pupils, fifty guineas. Clinical Lectures &c. are promised by all the physicians and surgeons, except Dr. Chambers.

Reception of patients on Wednesdays.—Operations on Thursdays at one o'clock. The physicians and surgeons are stated to attend almost daily at half-past twelve o'clock.

Dr. JEWEL will commence his autumnal lectures on *Midwifery and the Diseases of Women and Children*, at the Hunterian Theatre of Anatomy, Great Windmill-street, at 7 p.m. October 3, 1835. One course, three guineas; perpetual, five guineas.

Dr. ROBERTS will commence a course of Lectures on *Medicine*, on Monday, the 5th of October, at 10 a.m., at the House of Mr. Lunn, Chemist, corner of Westmoreland-street and Aldersgate-street. The terms of attendance, for one course, three guineas; perpetual, five guineas.

A Course of Lectures on *Midwifery and Diseases of Women and Children*, will be

delivered at 93, Bartholomew Close, near St. Bartholomew's Hospital, by Dr. Charles Waller, commencing on Monday, the 5th of October, at 4 6 p.m., and continued every Monday, Wednesday, and Friday, at the same hour. Terms.—Single course, three guineas; two courses, four guineas; perpetual, six guineas.

LECTURES ON *Medicine* will be delivered at the "Free Hospital, Greville-street, Hatton-garden," by Dr. Uwins, Senior Physician to the Hospital, commencing Oct. 1, at four o'clock, and continued every succeeding Mon., Tues., Thurs., and Fri., at 4 10 a.m. And Lectures on *Anatomy and*

Physiology, Pathology, and Surgery, will be delivered at the same place, by Mr. Greville Jones, Surgeon to the Hospital, commencing October 2, and continued daily at 24 p.m.

DISEASES OF THE SKIN.—An Institution, entitled the London Infirmary for the Treatment of Diseases of the Skin, is advertised at 51, Great Ormond-street, Queen-square; Dr. J. P. Litchfield, Physician; Mr. Carpine, Consulting Surgeon, Mr. H. Styles, Resident Surgeon, and it is stated that it will afford opportunities to students in medicine, for observing the nature and treatment of cutaneous diseases.

GENERAL DISPENSARY, 36, Aldersgate-street.—Physicians: Dr. Whitsea, Dr. Holt Yates, Dr. Rowley, and Dr. J. R. Bennett. The following terms of attendance are advertised:—For the period required by the Apothecaries' Company, 7*l.* 7*s.*; for six months, 5*l.* 5*s.*; for three months, 3*l.* 3*s.* But of course no student who wishes to learn anything of the practice of medicine, or has the slightest regard for his character as a professional man, will think of expending his money at this notorious establishment.

THE EAR—A course of Lectures on the Ear is advertised to be given at the Dispensary, 10, Dean-street, Soho, commencing at 7 p.m., Oct. 1, by Mr. J. H. Curtis.

LECTURES FOR APOTHECARIES' HALL.—Mr. W. Meade, 32, King-street, Borough, advertises a course of Lectures which is to embrace, in advantageous union, all the facts, and their relative bearing and connexion, which constitute subjects of examination at Apothecaries' Hall. Such a conspectus of medical knowledge may prove very useful to pupils as an introduction to their general studies. Mr. Meade also continues to give private instruction for the College and Hall.

Mr. TOASE assists gentlemen in their studies previous to their presenting themselves for examination at Apothecaries' Hall, at 4, Robert-street, Hampstead-road.

Dr. COLLIER will commence courses of Lectures on *Medicine* and *Materia Medica*, on Monday, October 5th, at 11 a.m., to be continued daily at the same hour, Saturday excepted, at 32, Spring-gardens.

At the Saint Pancras Infirmary, Dr. L. R. Willan will, in October, commence a course of *Clinical Instruction* and of *General Pathology*.

LECTURES ON *Materia Medica* and *Medical Jurisprudence* will be delivered by 'Mr. Barnes, at 72, Euston-square.

Materia Medica at a quarter before six o'clock p.m., on Mon. Wed. and Fri., beginning October 5. Fee for each six months' course, 4*l.*

Medical Jurisprudence at the same hour, on Tues. and Thurs. Fee for the whole course, 4*l.*

. Under the head of "Medical School, Westminster Dispensary," the following paragraph was accidentally omitted:—

The Lectures commence on Thursday, the 1st of October, at 11 in the morning, with a lecture by Dr. Ryan. Instruction in Morbid Anatomy is given by Mr. Wade, Surgeon to the Westminster Dispensary, and the gentlemen entering to the above lectures are admitted by Mr. Wade to his lectures, free from charge. Perpetual entry to all the lectures, thirty pounds.

HYGIENE AND MEDICAL JURISPRUDENCE.—A course of lectures on "Hygiene," the first occasion on which the subjects included under that title have been made the topics of lectorial discourses—is announced to be given this winter by Mr. Farr, a gentleman of ability and acquirements competent to the task, in the following advertisement, the latter division of the course involving the various branches of medical jurisprudence:—

"An Elementary Course of Hygiene and of Medical Jurisprudence, by Mr. Farr. The lectures on Hygiene will commence on Monday, October 19th; the second part of the course, embracing medical jurisprudence, will begin in January 1836. The course will be delivered at the Lecture-room, 8, Grafton Street, Fitzroy Square."

A course on "Hygiene" presents strong claims to the attention of medical men, and will, probably, from its novelty, obtain many attendants. The application of meteorology to medical science, the state of our knowledge of the influences of soil and climate, the history of the public health and of epidemics, and the statistics of medicine generally, ought not to be uninteresting subjects of consideration either to practitioners or students. The application of physical science to therapeutic investigation is daily becoming more frequent among philosophers, and as much valuable information has recently been brought to light relative to the hygienic operation of external agents, there has accumulated a considerable mass of important truths which demand to be made generally known, and may now be most usefully combined.

CHARING-CROSS HOSPITAL SCHOOL AND PRACTICE.*

COLLEGE OF SURGEONS.

The Council of the College of Surgeons enquire Candidates to bring proof—

1. Of being twenty-two years of age.
2. Of having been engaged five years in the acquirement of professional knowledge.
3. Of having studied Anatomy and Physiology, by attendance on Lectures and Demonstrations, and by Dissections, during two anatomical seasons. An anatomical season is understood to extend from October to April inclusive, and to comprise at least 140 Lectures on Anatomy and Physiology, occupying not less than one hour each, given on separate days; and at least 100 Demonstrations of the like duration, given in a similar manner; exclusive of Dissections, of which distinct Certificates are required.
4. Of having attended at least two courses of Lectures on Surgery, delivered in two distinct periods or seasons, each course to comprise not less than sixty Lectures.
5. Of having attended Lectures on the practice of Physic, on Chemistry, and on Midwifery, during six months; and on Botany and Materia Medica during three months.
6. Of having attended during twelve months the surgical practice of a recognised hospital in London Dublin, Edinburgh, Glasgow, or Aberdeen; or for six months in any one of such hospitals, and twelve months in any recognised provincial Hos-

APOTHECARIES' HALL.

The Board of Examiners at Apothecaries' Hall require candidates to attend the following Courses of Lectures:

Students whose attendance on Lectures shall commence on or after the 1st of October, 1835, will be required to produce proof of having attended Lectures during three Winter and two Summer Sessions, in the following order:—

The Winter Medical Session is to be understood as commencing on the first of October, and terminating in the middle of April, with a recess of fourteen days at Christmas; the Summer Session as commencing on the 1st of May, and ending on the 31st of July.

First Winter Session.—Chemistry; Anatomy and Physiology; Anatomical Demonstrations; Materia Medica and Therapeutics.

Second Winter Session.—Anatomy and Physiology; Anatomical Demonstrations; Dissections; Principles and Practice of Medicine; Medical Practice of an hospital.

First Summer Session.—Botany, and such other branches of study as may improve the student's general education.

Second Summer Session.—Botany, if not attended during the first summer session; Midwifery and Diseases of Women and Children; Forensic Medicine; Medical Practice of an hospital.

Third Winter Session.—Dissections; Principles and Practice of Medicine; Midwifery, with attendance on cases; Medical Practice of an hospital or dispensary.

The Student is also required to attend the Medical Practice of a recognised hospital, from the commencement of the Second Winter to the termination of the Third Winter Session, on a recognised Hospital.

The following are the PERPLEXATIONS, or "Regulations," which have been ordained at Rhuarb-Hall to bewilder those candidates for the license of the Company, who are severally circumstanced as below stated, and not now commencing their payments under the ticket-system for the first time:—

Students whose attendance on Lectures commenced prior to the 1st of February, 1828, will be admitted to examination in conformity with the Regulations published in September 1826, viz., after an attendance on

One Course of Lectures on Chemistry.

One Course of Lectures on Materia Medica.

Two Courses of Lectures on Anatomy and Physiology.

Two Courses of Lectures on the Theory and Practice of Medicine.

And six Months' Physician's Practice at an Hospital, or nine Months at a Dispensary.

Students who began to attend Lectures subsequently to the 1st of February, 1828, and previously to the 1st of October, 1828 (in conformity with the Regulations of September, 1827), will be admitted to an examination after an attendance on

One Course of Lectures on Chemistry.

One Course of Lectures on Materia Medica and Botany.

Two Courses of Lectures on Anatomy and Physiology.

Two Courses of Lectures on the Theory and Practice of Medicine: these last having been attended subsequently to the Lectures on Chemistry and Materia Medica, and to one Course at least of Anatomy.

And six Months, at least, Physician's Practice at an Hospital, or nine Months at a Dispensary; such attendance having commenced subsequently to the termination of the first Course of Lectures on the Principles and Practice of Medicine.

Students whose attendance on Lectures commenced in October, 1828, must have complied with the Regulations of September, 1828, viz., by having attended

Two Courses of Lectures on Chemistry.

Two Courses of Lectures on Materia Medica and Botany.

Two Courses of Lectures on Anatomy and Physiology.

Two Courses of Anatomical Demonstrations.

Two Courses of Lectures on the Theory and Practice of Medicine: these last having been attended subsequently to one Course of Lectures on Chemistry, Materia Medica, and Anatomy.

And Six Months, at least, the Physician's Practice at an Hospital (containing not less than sixty beds), or nine Months at a Dispensary: such attendance to have commenced subsequently to the termination of the first Course of Lectures on the Principles and Practice of Medicine.

Students who began to attend Lectures in January, 1829, are required to have attended the Physician's Practice at an Hospital for nine months, or at a Dispensary for twelve months, and also to have attended

Two Courses of Lectures on Midwifery, and the Diseases of Women and Children.

Students whose attendance on Lectures commenced on or after January, 1831, must adduce proof of having devoted at least two years to an attendance on Lectures and Hospital Practice; and of having attended the following Courses of Lectures:—

Chemistry.—Two Courses—Each Course consisting of not less than Forty-five Lectures.

Materia Medica and Therapeutics.—Two Courses—Each Course consisting of not less than Forty-five Lectures.

Anatomy and Physiology.—Two Courses—Of the same extent as required by the Royal College of Surgeons of London.

Anatomical Demonstrations.—Two Courses—Of the same extent as required by the Royal College of Surgeons of London.

Principles and Practice of Medicine.—Two Courses—Each Course consisting of not less than Forty-five Lectures,—to be attended subsequently to the termination of the first Course of Lectures on Chemistry, Materia Medica, and Anatomy and Physiology.

Botany.—One Course—Consisting of not less than Thirty Lectures,—to be attended between the 1st of April and 31st of October.

Midwifery and the Diseases of Women and Children.—Two Courses.

Forensic Medicine.—One Course—to be attended during the second year.

Students are likewise earnestly recommended to avail themselves of instruction in Morbid Anatomy.

The Candidate must also have attended, for Twelve Months, at least, the Physician's Practice at an Hospital containing not less than sixty Beds, and where a Course of Clinical Lectures is given; or for Fifteen Months at an Hospital wherein Clinical Lectures are not given; or for Fifteen Months at a Dispensary connected with some Medical School recognised by the Court. No part of this attendance can be entered upon until the termination of one entire year from the commencement of attendance on Lectures, nor until one course of Lectures, at least, on Chemistry, Materia Medica, Anatomy, and the Practice of Medicine, has been attended in the order prescribed by the Regulations.

Registration.—A book is kept at Apothecaries' Hall for the registration, at stated times, of the names of students, and of the lectures, hospitals, and dispensaries, to which they attend.

All students, in London, are required by the old Statute to appear personally, and to register the several classes

for which they have taken tickets; and those only will be considered to have complied with the regulations of the Court, whose names and classes in the register correspond with the testimonials of the teachers.

The book will be open for the registration of tickets authorizing the attendance of students on lectures and medical practice during the first twenty-one days of October, and first fourteen days of May, from nine o'clock until two; and for the registration of certificates of having duly attended such lectures or medical practice, during the last fourteen days of April and the first fourteen days of August.

Examination.—Every person offering himself for examination must give notice in writing to the clerk of the Society, on or before the Monday previously to the day of examination, and must also at the same time deposit all the required testimonials at the office of the beadle, where attendance is given every day, except Sunday, from nine until two o'clock.

The examination of the candidate for a certificate of qualification to practise as an apothecary will be as follows:—

In translating parts of Celsus de Medicina, and Gregory's *Conspectus Medicinæ Theoreticæ*.*

In Physicians' Prescriptions, and the Pharmacopœia Londinensis:

In Chemistry:

In Materia Medica and Therapeutics:

In Botany:

In Anatomy and Physiology:

In the Principles and Practice of Medicine.

The examination of a candidate for a certificate of qualification to act as an assistant to an apothecary, in compounding and dispensing medicines, will be as follows:—

In translating Physicians' Prescriptions, and parts of the Pharmacopœia Londinensis:

In Pharmacy and Materia Medica.

By the 22nd section of the Act of Parliament, no rejected candidate for a certificate to practise as an apothecary, can be re-examined until the expiration of six months from his former examination, and no rejected candidate as an assistant until the expiration of three months.

* Students may undergo their Latin examination in these works at the commencement of their studies in London, by giving notice to the beadle, at their first registration, of their wish to do so. And students who are already registered will be admitted to the examination on making an application to the beadle.

This branch of the examination embraces an intimate knowledge of the diseases of pregnant and puerperal women, and also into the diseases of children.

The Court meet in the Hall every Thursday, where candidates are required to attend at a quarter before four o'clock.

For information relative to these regulations, students are referred to Mr. Watson, who may be seen at his residence, 43, Berners Street, between the hours of nine and ten o'clock every morning (Sunday excepted).

It is expressly ordered by the Court of Examiners, that no gratuity be received by any officer of the Court.

THE LANCET.

London, Saturday, September 26, 1833.

IN some of the preceding pages of the present Number of THE LANCET will be found the announcements of the Medical Schools for the Session 1835-36. The statements which we have printed are taken from the prospectuses which have been issued by the conductors of the various establishments. We are not answerable, therefore, for what we have inserted, further than concerns the accuracy of our extracts. Heaven forbid that we should be answerable for the promises and pretensions of the lecturers! The bills of fare for the present year are, for the most part, screwed up to the last turn of extortion, in perfect consonance and keeping with the regulations which have been recently issued by the Apothecaries' Company. Oh those drug-dealers of Rhubarb Hall! They will receive a dose of physic soon from another establishment, the effects of which will be permanent, both upon their constitutions and their coffers. Never was there endured, in a civilized country, a more abominable system than that which affects to lecture a student into a knowledge of the practice of medicine and surgery. In the absence of statutory enactments no such abomination could have existed even for five years. It would have been broken down under the pressure of its own guiltiness. It is made up of falsehood, fraud, and avarice. Still, the students must bend to the existing re-

gulations,—must submit to be duped and plundered,—or they cannot, according to the decisions of some of our judges, become legally-qualified practitioners of medicine in any part of England or Wales. The moment, however, that they obtain their qualifications, they have it in their power, by the positions which they are enabled to occupy, to contribute towards the overthrow of the system which, for a time, they are compelled to support by their unwillingly-paid funds. We call upon them, therefore, to conform strictly to the “regulations” of the Boards of Examiners. And this demand upon their patience and good temper is made in the hope of seeing them turn, as hundreds of their predecessors have turned, with vigour and boldness, upon the monopolists and the extortioners, for the purpose of effectuating that general smashing of the medical *lecturing* concerns, which have not only sprung up in the metropolis, but are now springing up, like so many foul fungi, in every part of the British empire. Is it not the boast of all our writers on medicine and surgery, that, from the seventeenth to the eighteenth century, the science of medicine had advanced with the most rapid steps of improvement? And yet,—hear it, ye lecturers and pretenders!—there neither existed then, nor in 1714, any such preceptory system established by law as exists now. Let those surgeons who are engaged in the practice of their profession in our country towns, and who have faithfully discharged the obligations imposed on them by the indentures of their apprentices,—let those surgeons, we say, refer to the bills of fare exhibited in the preceding pages,—to the charges for the stale and stolen hashes of words which the students are compelled to purchase in this metropolis, or be excluded from the pale of the profession. Let them observe, also, that no distinction whatever is made by the colleges, hospitals, and schools, between the instructed and uninstructed applicant. The young man whose mind is well stored with a knowledge of the principles and practice of his profession, is compelled to expend as

much time and money in this metropolis upon lecturing and ward-walking, as the individual who has never devoted an hour of his life to the consideration of professional subjects.

Why, rather than that such a system as this should continue to flourish, it would be preferable for our hospitals and schools to be swept from the face of the earth. Why is the knowledge which the country surgeon communicates to his pupil, treated as nought by the extortioners of our colleges and companies? It is one of the grossest insults that was ever offered to a body of educated men. By the existing regulations, all the medical students in the kingdom, unless they have paid certain sums of money to other schools where the system of folly and of falsehood is carried partially into operation,—all the students, without exception, we repeat, are treated as so many dunces,—as mere beginners in the rudiments of medical education. What doctrine does this inculcate to the community? Why, that those surgeons who take apprentices are incapable of instructing them even in the very elements of professional knowledge. Thus, in the course of years, they are deprived of those fees which they are entitled to receive from their apprentices, because parents and guardians, naturally enough, contend, that if the knowledge which the student derives during his apprenticeship does not *lessen* the expense of a medical education in London, the money paid for the pupilage in the country is, virtually, thrown away. Thus a flagrant robbery is committed on the great body of surgeons and apothecaries who are engaged in private practice, and a most shameful injustice is inflicted on the student, who, during his apprenticeship, and under the able and generous guidance and instruction of his master, has succeeded in obtaining a practical and scientific knowledge of his profession. With what show of reason can it be contended that the *ill-treated* individual apprentice should be treated on precisely the same terms,—that no restraint should be

imposed on the one,—that no privilege should be awarded to the other?

"Oh, but there are prizes given in the schools! Look," some blockhead may exclaim, "at the splendid announcement of prizes which has just been made in the prospectus of the St. Bartholomew's school!" Bah! It is all humbug and quackery, *and the lecturers know it*. When are the prizes awarded? Certain enough, at the *end* of every session, when the last shilling has been extorted from the pockets of the student! And of what do the prizes consist? Why of "Books," written, we suppose, by the STANLEYS, the EARLES, the VINCENTS, and geniuses of that class. If anything could display effectually the monstrous character of this PRIZE FARCE, which has just been got up as the new catch-fee of the day, it might be seen in this fact,—that out of the class which attends *St. Bartholomew's Hospital*, not less than *thirty-seven* students,—*thirty-seven!*—obtained at one examination "prizes" and "certificates of honour;" and, to complete the picture of absurdity, the distinctions were distributed by that knowing man MATTHEW PRYME LUCAS, Esquire, Alderman of the City of London, —a somewhat better judge, we take it, of *turtle*, than of the quality of medical attainments. If the lecturers had introduced the practice of awarding prizes on the ground of rewarding *merit*, alone, by instituting a free and open competition amongst all classes of medical students, they would have established fellowships, or scholarships, in their schools, and would render the successful competitors free to the hospital and classrooms during their sojourn in the metropolis. In a mental point of view, we admit, this may be no reward; but it might relieve, at any rate, some of the students from a payment of fifty or sixty pounds for tickets which are of no other value than that of being instrumental in the procurement of so many "recognitions" and "participations."

But we contend that every surgeon in the land has an undoubted right not only to

qualify his pupil for the practice of the profession, but to insist, at the expiration of the apprenticeship of the pupil, that he shall be admitted to an examination for the diploma of the College, or the license of the Hall. After what has occurred we know that the right would be disputed by many of our legal authorities. Hence it is that we would entreat the whole of our medical students to comply with the terms which are laid down in the "regulations" of the examining bodies. The triumph of *principle* is about to be acknowledged. This, therefore, is not the time for making stumbling-blocks out of collegiate forms, or for hesitating relative to the payment of a sum of money which is unjustly demanded, when it is quite certain that a non-acquiescence with regard to that demand may be converted into an instrument for one's own ruin. A judicious course of policy, therefore, requires that the students should comply with the conditions of the bonds which have been framed for their "*benefit*" by the heads of our Colleges and Schools. At the same time they are bound to see that the other contracting powers do not escape from the conditions which are obligatory on *them*. Punctuality of attendance should in all cases be enforced, and where promises which have been made in the prospectuses are not redeemed in practice, the delinquents should be at once unhesitatingly exposed.

It should be observed, that we do not direct our strictures against individuals, but against the odious ticket-system generally. We complain not so much of the lecturers as a body, as of the incorporated monopolists who have originated and sustained the LECTURING ABOMINATION for their benefit. That some of the teachers, and several of the hospital surgeons, are men of capacity and skill, we freely and cheerfully admit; but they do not command our respect, because they resistlessly allow themselves to be dragged through the mire by authorities which they have it in their power to con-

trol. We do contend, however, that the principles and practice of medicine cannot be taught by means of oral addresses. We care not what may be the lecturer's capabilities of speech,—what may be the extent of his information and his experience. It is not possible to convey correct impressions of disease to the mind through the ear, which should be imparted through the medium of another sense. The eye must be employed. The deviations from normal structure and function must be seen, before they can be adequately understood. Until, therefore, the rights of all medical men are placed on an equal footing with respect to the privilege of educating youths for the practice of medicine, we shall continue to exercise, fearlessly and unremittingly, whatever influence we may possess, in the hope of demolishing the ticket and certificate system of our incorporated hospitals and recognised schools.

(From a Correspondent.)—On Wednesday last an apothecary was elected by ballot (not by concurs) at *Westminster Hospital*.

The numbers were as follows:—

Mr. Thurnam	102
Mr. Alfred Hall	68

Majority for Mr. Thurnam 34

Mr. Thurnam, a member of the society of Friends, was the protégé of the Artillery party, of whom Dr. Hallam is the great gun, and Dr. Wood the chief bombardier. As the mode of election had nothing to do with the merit and competence of the party to fill the office, we have no one to congratulate on the result of the competition.

A GREAT meeting of the medical men residing in the Eastern part of England was appointed to be held at Bury St. Edmunds yesterday, Friday, the 25th inst., for the purpose of forming an Eastern Provincial Medical Association. The names of 150 medical gentlemen were attached to the requisition by which the meeting was called. The system of Poor-law contracts has been the originating cause of the requisition.

UNIVERSITY OF LONDON AND COLLEGE OF SURGEONS.

To the Editor of THE LANCET.

SIR,—Your comments on my letter of last week induce me again to address you. "You much doubt," you say, "if two things more unlike than the admission to

an examination for a surgical diploma and the admission to compete for a chair in a medical school were ever before compared." Things may be unlike, while the principles whence they result admit and require comparison. Your remarks necessarily lead me to inquire on what principles the London University, and on what principles the College of Surgeons, were founded, and ought therefore to have been conducted. It will then be seen in which of the two bodies the conductors have most deviated, and in what direction, from those principles. The London University was established, and the sum of 100,000*l.* was subscribed, for the advancement and promotion of literature and science, and for the purpose of affording opportunities of attaining such branches of knowledge as were not previously taught in London; and it was declared that candidates for professorships should be treated with such strict regard to justice, that a difference in competency, even so slender as the hair that turns the balance, should determine the choice. Have these principles really been acted upon? The facts will speak for themselves. A large portion of the funds was expended upon a building, of which the dome alone cost about 20,000*l.* That building has since been mortgaged partly to erect an hospital, the officers to which were appointed without even the form of an election. Those branches of science, such as moral philosophy and jurisprudence, which required endowment and support, and which it was one of the first objects of the proprietors to cause to be cultivated, have been left unprotected. The professors, who should have been elected with such nice regard to justice, were chosen in a manner the least conducive to justice and impartiality. If these things have resulted from the management of the London University, its conductors must have deviated from the principles on which it was founded, and surely the deviation has been in the wrong direction. After this turn to the College of Surgeons.

That corporation was embodied by charter, and if its conduct has been in accordance with the principles of the charter, the Council must stand acquitted of the serious charges of misgovernment which the directors of the London University have incurred. More than this: it cannot be denied that the changes made of late years by the College of Surgeons, have been marked by increasing justice and liberality; and, to revert to the case in question, the Council there acted upon principles more liberal than the charter itself seems to have prescribed, while the Council of the London University acted in a manner diametrically opposite to those principles of justice and liberality on which the institution was founded. The former might not be bound by the charter to admit me to examination and to receive

CLINICAL LECTURE

ON CASES OF

INJURIES OF THE ABDOMINAL

AND

PELVIC VISCERA.

BY

ANDREW ELLIS, Esq., M.R.C.S.I.,

Surgeon to the Jervis Street Hospital, and Lecturer on Surgery in the School of Anat., Med., and Surg., Peter Street, Dublin.

GENTLEMEN,—I beg your attention whilst I read an abstract report of a few cases which bear on the subject of the symptoms, pathology, and treatment, of injuries of the abdomen, and which have been selected from the case-book of the hospital for the purpose of illustrating those points.

CASE 1.—*Stabbing Wound of the Stomach.*—John Lawless, aged 26 years, was admitted into the hospital at nine o'clock p.m., on the 28th of December, in consequence of his having been stabbed with a knife by his brother, with whom he had been quarrelling. On admission he appeared to labour under the combined effects of the wound and drunkenness: he was weak, with pale smoken countenance, and quick pulse; he vomited repeatedly a considerable quantity of blood mixed with food. The wound was situated near the umbilicus; it was about an inch and a half in length, and through it a piece of intestine of a pinkish colour protruded. The patient was now put to bed, and an attempt made to reduce the intestine, but this it was found impossible to accomplish in a perfect or satisfactory manner: it could be returned with moderate facility through the wound in the integuments, but instead of passing through the opening in the peritoneum and thence into the cavity of the abdomen, it went into a pouch or recess formed between the membrane and the abdominal muscles. During the efforts made to restore the intestine, he was very restless and unmanageable, holding his breath, and otherwise resisting the efforts made to relieve him. It was now deemed advisable to have an enema administered, and a vein opened in the arm: when about twenty ounces of blood were drawn, the bowels were affected, and he became quite exhausted and pulseless, the skin being covered over with cold perspiration. Whilst in this state of syncope, the protruded intestine was returned into the cavity of the abdomen without any difficulty; and the lips of the wound were kept together by two points of suture, supported by a compress and a

bandage, which was applied with a moderate degree of tightness. This being done, the patient was placed in a posture calculated to relax the abdominal muscles.

29. He has slept but little during the night, vomited three or four times, and complains of exquisite pain in the abdomen, which obliges him to scream whenever he makes a full inspiration: he cannot bear to be moved or touched in the slightest degree; the countenance is sharp and anxious, tongue brown; excessive thirst; pulse 140, and no secretion of urine. He was bled again to the amount of thirty ounces, and ordered three grains of calomel and half a grain of opium every hour.

2 o'clock p.m. The bleeding produced fainting; he has been exceedingly restless since the last visit, and suffered much from thirst and vomiting; the bowels have been moved, but no secretion of urine has taken place; at present he lies in rather a torpid state, with much heaving of the chest; the respirations are forty in a minute; the pulse is exceedingly quick and almost imperceptibly small.

30. He died at six o'clock yesterday evening.

Autopsy.—On examining the body sixteen hours after death, it presented the following appearance. There was a small quantity of blood, but no food, effused into the cavity of the abdomen; and a wound about half an inch in length was found in the stomach, situated two inches from the pyloric orifice, and, consequently, much above the level of the external wound. There was no other viscus wounded, and the usual effects of peritoneal inflammation were but imperfectly marked.

Remarks.—There are a few points connected with this interesting case to which I beg to call attention. In the first place, it may appear to you somewhat strange, that the stomach should be the only organ wounded when the knife had entered the abdomen so low down as the umbilicus; however, when you call to mind that the situation occupied by the stomach must in a great measure be determined by the various degrees of plenitude or vacuity to which it is liable, that which, at first blush, appeared abstruse and unaccountable, becomes at once simple and intelligible. Now, be it remembered, that this unfortunate man had been drinking before the accident occurred, and that he subsequently vomited up food as well as blood. Under these circumstances, it is obvious that the stomach was distended, and consequently encroached on the umbilical region, at the moment the wound was inflicted, but when discharging its contents it contracted, and thereby withdrew itself from the external wound.

The fact of none of the contents having escaped into the cavity of the peritoneum,

is a strong proof of the accuracy of the explanation I gave you (*LANCET*, No. 629, page 753, when speaking on the subject of abdominal extravasations, and the steps taken by nature to prevent their occurrence in cases of wounds of the hollow viscera. The influence of the enema and blood-letting in facilitating the return of the protruded intestine, reminds us of what we frequently see take place in cases of strangulated hernia.

The state of syncope to which the patient was reduced by loss of blood, had the effect of producing general relaxation, and, consequently, of overcoming the muscular action which originally forced out the bowel, and subsequently resisted its return; whilst the enema, by exciting the inverted action, or antiperistaltic motion of the intestines, contributed to its replacement. It has been very properly noted down that the usual effects of peritoneal inflammation were but imperfectly marked; I am disposed to attribute this circumstance to the early depletion the patient underwent, and the short time he survived after the accident. You may recollect that the wound itself gave rise to a very considerable hemorrhage, and that, in addition, forty or fifty ounces of blood were taken by the lancet in the course of a few hours afterwards. On the whole, I should be inclined to account for his death by saying that the constitution sympathetically sunk, both in consequence of the loss of blood, and the serious injury done to a very important organ, rather than state that peritoneal inflammation was the immediate cause of dissolution.

CASE 2.—Crushing of the Abdomen.—Rupture of the Cecum.—The next case to which I wish to call your attention is that of J. Donohoe, a drayman, who on the 6th of July, whilst leading his horse through the street, was caught, and severely crushed, between the wheel of his own and that of another dray, which were passing in opposite directions. Soon after the accident he walked to the hospital, where he arrived at two o'clock p.m. Having got some instructions and medicine, he walked home and went to bed. In the course of the evening he was seized with violent pain in the abdomen and vomiting, which continued during the night. On the morning of the 7th he was carried to the hospital, being now totally unable to walk; his countenance was pale, anxious, and indicative of great suffering; the skin was cold and clammy, and the pulse could not be felt at the wrist; the abdomen was tense, and would not bear the slightest pressure; the vomiting had ceased, and he was incessantly tormented with an insatiable desire for cold drink. The usual treatment for such distressing symptoms was employed, but in vain; the poor fellow died at eight o'clock the next morning,

being twenty-four hours after admission, and forty-two after the receipt of the injury.

Autopsy.—On opening the body, four hours after death, the following appearances were discovered in the cavity of the abdomen:—The intestines were distended with flatus, and the peritoneal coat was of a bright rose colour, except where covered with lymph, which was shed in great quantity. The cecum was dark-coloured and thickened in its coats; it presented at its lower extremity an aperture, with irregular ragged edges, merely of sufficient size to admit the extremity of the little-finger. There was no extravasation of feculent matter.

Remarks.—It may appear remarkable that in this case the patient was able to walk to and from the hospital soon after the accident occurred; and that it was not until some hours afterwards that he was attacked with bad symptoms; whereas, in the case of Lawless, violent symptoms were established at the moment the wound was inflicted, and continued without intermission until he died. In reference to this point I beg to observe that it is a fact, very generally admitted, that the degree of shock imparted to the constitution in consequence of injuries of the abdomen, is in the direct ratio of their relation to the solar plexus; that is to say, the nearer the injury is to that important and vital part, the more deeply will the constitution sympathize at the moment of the accident, and the greater the danger to be apprehended, as to the ultimate termination of the case. If you acquiesce in the correctness of this doctrine, you can readily comprehend why Lawless, who was wounded in the stomach, got no quarter from the moment of the accident; whilst Donohoe, whose cecum was ruptured, did not suffer from bad symptoms for some hours after the infliction of the injury, when peritoneal inflammation set in, and finally became the more immediate cause of death. Allow me again to remind you of the fact, that Lawless lived but sixteen hours after he received the wound, and on examination of the body it was ascertained that the usual effects of peritonitis had been but imperfectly established; we must, therefore, infer that in this instance the patient sunk partly from loss of blood, but more especially from the direct effects of the injury on the system at large; or, in other words, from what Mr. Travers would call "constitutional irritation." I will now read a case which tends to support the validity of the opinion already expressed as regards the influence which the relation of the solar plexus to the local mischief may have in a case of abdominal injury.

CASE 3.—Crushing of the Abdomen.—Rupture of the Duodenum.—On the 14th of July, Eliza Healy, aged four years

thrown down in the street by a dray, the wheel of which passed over her body; she was carried to the hospital in about an hour afterwards; on admission she was exceedingly weak and exhausted; the countenance pale and the eyes sunk; the pulse quick and almost imperceptibly small; she seemed unwilling to answer questions; was extremely restless, constantly tossing her limbs about in the bed; she drank with avidity, had frequent retching, but nothing came up from the stomach; there was no tenderness of the abdomen. She gradually became more and more exhausted, and expired in four hours after her admission into the hospital.

Autopsy.—On examination twelve hours after death, the peritoneum presented a healthy appearance, but a few cherry-stones, mixed with alimentary matter, were found in its cavity. When these substances were removed, a small rent was discovered in the descending portion of the duodenum, through which they had escaped. The lower extremity of the spleen was likewise ruptured, there was however very little blood extravasated; all the other viscera were perfectly natural.

Remarks.—You will observe that this was a case in which the injury was situated quite in the neighbourhood of the solar plexus, and that the patient never recovered from the first shock of the accident; the immediate cause of death cannot, therefore, be fairly attributed either to loss of blood or peritoneal inflammation.

The next cases for our consideration are those of ruptured bladder, but before we discuss them individually, I feel that a few observations on the subject of urinary extravasations in general would not be misplaced, and that they might be instructive to the junior part of my hearers.

Urinary extravasations may be suddenly produced either by blows or falls on the perineum; or on the abdomen, if the bladder should happen to be distended at the time of the accident. For example, let us suppose a case in which a sportsman, whilst in the act of riding his horse over a fence, loses his stirrup, and is, accordingly, thrown forward on his perineum with all his weight against the pommel of the saddle. Now, in a case of this description, there is much reason to suspect that the urethra has been ruptured; should blood pass from the external orifice soon after the accident, the patient in attempting to pass water feels as if he were emptying the bladder, yet none escapes externally; and if the attempt were attended with a swelling of the scrotum, there can be no doubt but extravasation has already taken place. If this case be not promptly and properly attended to, very bad consequences will most certainly ensue; the scrotum, and perhaps the penis and prostate, will become enormously tumefied, and assume a dark-red colour; gan-

grenous spots will appear on the integuments, through which, should the patient survive, sloughs of the cellular membrane, saturated with a mixture of urine and ill-conditioned matter, will escape. Whilst these changes are taking place locally, the patient's constitution suffers severely; symptomatic fever becomes quickly established, he feels hot and restless; complains of headache and thirst; the tongue is covered with a brownish tenacious matter; the secretions generally are diminished; and the pulse is very frequent. As the case advances, all these symptoms become worse; delirium and coma set in; the tongue is now dry, black, and contracted; the skin is often at this stage of the complaint covered over with a urinous sweat; the pulse becomes exceedingly small and intermittent; and, finally, death closes the scene.

If the description I have now given of the usual effects of urinary extravasations caused by rupture of the urethra be correct, you must at once perceive the necessity of attention and decision on the part of the surgeon, and the fatal consequences which are likely to ensue, either from diffidence, hesitation, or ignorance, on his part. You should keep constantly in mind the pernicious effects produced by urine when brought in contact with any of the living animal textures, save the skin and mucous membranes. In accordance with this view of the subject, you should consider such a case as I have supposed to occur to be of local origin, but of a most dangerous tendency; you should, therefore, when called on, in the first instance, apply yourselves to the source of the evil.

Taking this view of the subject, the practitioner, when satisfied that extravasation has actually taken place into the cellular membrane of the perineum and scrotum, should introduce a silver catheter as far as he can, without using much force, into the urethra; in all probability that will be down to the laceration; he should now with a knife or scalpel make a free incision through the tumefied parts, until he has exposed the catheter at the rupture in the urethra. By this means the urine already effused will be drained out of the cellular membrane, and in the event of any more escaping from the aperture in the urethra, it will have a ready exit, and therefore will not become diffused through the neighbouring parts. This being done, the metallic instrument should be withdrawn, and a gum elastic catheter should be introduced into the bladder, and retained there by a suitable apparatus; a poultice is next to be applied to the wound. Suppuration, and probably sloughing, will take place to a certain extent. The catheter should not be removed, except for the purpose of clearing away the calcareous incrustations which usually form on

its vesical extremity, until the breach in the urethra shall be completely closed up. The constitutional treatment of a case of this description must vary in different instances, and be determined, in a great measure, by the sort of person affected, the character of the symptoms, and the stage of the complaint. For example; if the accident happened to a plethoric young man, and was succeeded by the ordinary symptoms of inflammatory fever, there can be no doubt as to the propriety of employing antiphlogistic remedies in the first instance; but let us now suppose the case to be far advanced, the scrotum in a decidedly sloughy state. The constitutional symptoms here change their character, and resemble those of a bad typhus fever. Here the constitutional plan of treatment should consist chiefly of stimulants and tonics: such as camphor, carbonate of ammonia, with small doses of opium. Mild nutritious wine, such as claret; or if the patient were in the habit of indulging largely in malt drink, porter or ale may be administered with advantage. I have never found bark in any form useful, nor do I believe that it does much good in any case where the tongue is covered with a dark dry crust, and the stomach disposed to nausea or irritability. The best local applications for this stage of the case, are warm dressings, and the fermenting poultice.

I have just now placed before you, in a familiar manner, the ordinary symptoms and treatment of a case of extravasation of urine, having supposed it to arise in a healthy young man, in consequence of a rupture of the urethra. Let us now take another view of the subject, and assume that the accident had happened to an old fox-hunter of dissipated habits and broken-down constitution, and inquire if the symptoms and treatment would, or ought to be, precisely the same in both cases. There certainly will be no remarkable difference in the local symptoms, and they should be treated by the catheter, incision, and poultice, as in the former case; but the antiphlogistic plan of treatment will not be applicable in this instance at all; on the contrary, the patient should be watched closely from the commencement, and as soon as symptoms of debility shall appear, the treatment I have recommended for the second stage of the former case should be at once adopted in the latter.

You will occasionally meet in practice, cases of extravasation of urine in children, and inasmuch as they differ in some respects from those I have described as taking place both in young and old men, I feel it my duty to make a few observations on this subject.

The usual cause of extravasation in children, is the giving way of the urethra, in consequence of a small calculus having become firmly impacted in it when on its way from the bladder. The breach in the canal is sometimes effected by rupture, in conse-

quence of the great straining produced by the irritation of the foreign body, and the urgent desire to pass water, which is now mechanically resisted, and at other times it is, I believe, the result of ulcerative absorption, which has not been preceded by the adhesive inflammation. However, be that as it may, my present object is merely to apprise you of this fact, that the urine of children, being chiefly composed of water does not, when extravasated so speedily, produce the same destructive consequences to the cellular membrane through which it may be diffused, as in the cases of adults, or old persons, which I have already described. When apprising you of this pathological fact, I do not wish to convey the idea that you should be less vigilant or attentive in your treatment on that account; on the contrary, the cause of extravasation (the calculus) should be removed as quickly as possible, and a free incision made into the distended parts, in order to allow the effused urine an opportunity to ooze out of the cellular tissue with which it has commingled. I pronounce the word "ooze" emphatically; for you must not expect, that a sudden gush of urine will take place when an incision is made into the affected part; this never happens unless the extravasated fluid is confined in a circumscribed cavity, which does not often occur. After the incision a poultice should be applied, but I never found it necessary to introduce a catheter in the case of a child; and, indeed, I think it a very fortunate circumstance that such a procedure can be dispensed with; for, if it were absolutely necessary, it would be extremely difficult, if not impossible, to retain it quietly in the bladder. The observations which I have now made refer merely to such urinary extravasations as occasionally take place external to the abdomen and pelvis. I trust I have said sufficient to prepare you for the fatal consequences which are to be expected when similar effusions occur within those important cavities. With a view to illustrate this part of our subject, I beg to call your attention to a few cases of ruptured bladder.

CASE 1.—Rupture of the Bladder from a blow.—William Corry, aged 26 years, a carrier by trade, was admitted into the hospital on the 19th of March, at 11 o'clock p.m., under the following circumstances. When brought to the hospital he was stupidly drunk; his friends stated, "that he had been drinking all the day, and that towards evening he had suffered much from a desire and incompetency to pass water; that he subsequently got into a row, and that they believed he had been struck on the belly with a watchman's pole." It was quite impossible to obtain any information from himself; but Mr. Cullen, who admitted him, mentioned "that Corry was subject to an

tacks of retention of urine, from spasmodic stricture, when he was guilty of any debauch, and that he had frequently relieved him by drawing off the urine." On examining the abdomen, it did not appear to be particularly full or tense; however, it was deemed expedient to introduce a catheter, but no urine came away. The stomach pump was next employed and brought up a large quantity of liquid, which appeared to be a compound of whiskey and porter. He was now placed in bed, and immediately fell into a heavy sleep.

20. He slept soundly during the night, but is at present very feverish; complains of pain in the lower part of the abdomen; is affected with headache, foul tongue, thirst, heat of skin, quick pulse, and inability to pass water. The catheter was introduced, and drew off about a pint of healthy urine; he was bled, purged, stuped, &c. &c., yet his sufferings were mitigated only in a trifling degree. The fever continued for two or three days, without undergoing any important change; at the end of this time the retching, which had been moderate and occasional, now became distressing, and almost constant; the abdomen was very unid, tympanitic, and tender to the touch; his breathing was hurried and oppressed; he was exceedingly restless, and occasionally suffered from hiccup, and had a constant desire to pass water. These symptoms were met as the circumstances of the case seemed to indicate; blood-letting was frequently had recourse to, both by the lancet and leeches; blisters were applied, and the mouth was slightly affected with calomel; the catheter was introduced three or four times every day, but never brought away more than an ounce of urine at any one time, excepting on the second day after his admission into the hospital. All the symptoms gradually grew worse; the countenance became exceedingly sharp, and expressive of internal distress; the pulse very small, and the abdomen enormously tumid; there was much general emaciation and debility; and on the fifteenth day after the accident, death put a period to his protracted and exquisite sufferings.

Autopsy.—On opening the abdomen six hours after death, the following appearances were discovered. The intestines were very much distended with flatus; the peritoneum was but slightly vascular, with a few small patches of lymph on its surface; however, the cavity contained between two and three gallons of pale urinous fluid. On examining the bladder, a vent, capable of admitting the extremity of the little-finger was found in its superior and posterior part, where, covered by peritoneum, the margins of the opening did not present anything remarkable, being rather thickened nor everted. The abdominal viscera were otherwise

CASE 5.—Rupture of the Bladder from a Fall.—James Cod, aged 28 years, a servant; whilst riding a spirited horse on the evening of the 31st of August, the animal became restive, reared up, and fell backwards on the rider. He was much shocked at the time, felt weak, and sick, and was immediately conveyed home and bled by an apothecary; in about two hours after the accident he was brought to the hospital, and on admission he looked pale and anxious, his skin was cold and his pulse slow and weak; he expressed a desire to pass water, but was incapable of doing so. It was ascertained that he was tipsey at the time of the fall, and that he had not evacuated his bladder for a considerable time before it. He was placed in bed, and a catheter was introduced, but nothing came away but a small jet of blood.

Sept. 1, five o'clock a.m. He is very restless, complains of intense pain all over the abdomen, and is much tormented with hiccup. He was ordered twenty-four leeches to the abdomen, their application to be followed up by warm fomentations.

Twelve o'clock. The symptoms have increased in violence: the abdomen is very tense, and exquisitely painful; the pulse 120 and hard; the bowels confined, and the desire to pass water urgent. The catheter was again introduced, and brought away nothing but a small quantity of blood. He was ordered to be bled from the arm to the amount of ten ounces, and to have forty leeches applied to the abdomen, and an emollient injection.

Five o'clock. The leech-bites bled profusely; the bowels have been freed, and he passed a small quantity of urine without the catheter; the pain in the abdomen is less severe.

Sept. 2, nine o'clock a.m. Bowels free; passed some urine; pain in the abdomen inconsiderable; however, the prostration of strength is very great.

Five o'clock. He seems to be quite exhausted, with sunken countenance; cold perspiration; pulse scarcely perceptible, about 150 in a minute; respiration 60, and laborious; he still complains of some pain in the abdomen.

3. He died at six o'clock yesterday morning.

Autopsy.—The abdomen was examined three hours afterwards. It contained about a quart of reddish fluid, which emitted a urinous smell: the peritoneal coat of the intestines was vascular, but there was no effusion of lymph. On introducing a catheter into the bladder, it went through a small aperture in the superior fundus, into the cavity of the peritoneum; the margin of the opening was somewhat thickened, and the parts of the bladder immediately around it

bladder itself was perfectly empty, and contracted into a firm ball.

Remarks.—I have thus read to you two very interesting cases of ruptured bladder, together with a description of the appearances exhibited at the post-mortem examinations; and now, before we separate, I wish to make a few general observations regarding those cases. In the first place it must appear somewhat strange to you, that the bladder should have given way in both instances in that part which is covered by peritonæum. Now, this is not a mere accidental or coincidental circumstance, for, in every case that I am acquainted with in which the bladder gave way in consequence of falls or blows on the abdomen, the rupture took place in the peritoneal region of the organ. In support of this statement, I beg to refer you to two very important cases of this description, which have been published in the second volume of the "Dublin Hospital Reports," by Doctor Cusack. The only explanation I would venture to suggest, is the anatomical fact, that the superior and posterior regions are weaker than the other parts of the bladder; inasmuch as they do not receive any support from the reflections of the pelvic fascia; whilst the peritoneal covering, which is comparatively thin and delicate, and being, in common with all serous membranes, devoid of elasticity, it is, therefore, incapable of accommodating itself to violence suddenly applied; consequently it yields only by the laceration of its proper structure.

The next point to which I am anxious to call your attention, is the difference which exists between the local consequences that result from urinary extravasation into the cellular and serous tissues. I have already mentioned to you that inflammation and mortification are the usual effects when it takes place in the cellular membrane; now I beg to state that in no one instance with which I am acquainted did mortification ensue from urinary extravasation into the cavity of the peritonæum. Judging from the usual effects of injury or irritation on that very delicate and sensitive membrane, it appears to me very extraordinary that in cases of ruptured bladder, in which the peritonæum is wounded and brought in contact with a very acrimonious fluid, it should be rather slow in taking on inflammatory action, and capable of effectually resisting its gangrenous consequences. In the case of

Cod, which ended fatally on the third day after the accident, the usual effects of peritoneal inflammation were but imperfectly marked; and in the case of Corry the patient lived to the fifteenth day, and the post-mortem appearances would scarcely warrant us in saying, that the distressing symptoms under which he laboured during his illness were solely the result of peritonitis. Dr. Cusack's patients died on the eighth day after the accidents, and the appearances presented by dissection were, with the exception of the unnatural vesical openings, and the consequent urinary effusions, those usually resulting from peritoneal inflammation.

Gentlemen, here I wish to apprise you of what, in my judgment, is a very erroneous opinion, as regards the state of the peritonæum in fatal cases of inflammation of this membrane. It is generally stated by authors who treat of peritonitis, that the sudden cessation of pain, which usually precedes a fatal termination, is a sure sign that mortification has actually taken place. Now, I wish you to understand that my experience of this disease, and the dissections I have made of persons who have died of it, induce me to arrive at an opposite conclusion. With the exception of one or two instances, I have never been able to find gangrenous spots in the peritonæum, when examining the bodies of persons who have died of inflammation of that membrane; I am, therefore, disposed to think that it would be more in accordance with the principles of correct pathology, to consider this absence of pain as indicative of a fatal loss of sensibility, rather than a positive assurance of structural disorganization, and chemical decomposition. For my own part, although it may, perhaps, appear too figurative to say so, I look on the sudden subsidence of pain in those cases, as the incipient ebb of vitality; or, if you will, the first stage of death.

The reason why serous membrane is more capable of resisting the gangrenous effects of inflammation than cellular membrane, in cases of urinary extravasation, is in my mind easily explained by reference to the relative degrees of vitality, which they both possess. When you consider that the former is much more highly organized than the latter, you will not feel surprised to hear that the peritonæum may resist the disorganizing consequences of an inflammation which would prove destructive to the component parts of the scrotum. Gentlemen, you may probably consider that my observations to-day have been of a very desultory and heterogeneous character, but when you reflect upon the variety of topics, and the numerous cases, which I felt it my duty to discuss, I trust you will not deem them misplaced.

CASE OF CATALEPSY

COMPLICATED WITH

HYSTERICAL SYMPTOMS.

To the Editor of THE LANCET.

SIR,—Having read with considerable advantage the two cases of catalepsy recently reported in THE LANCET, I am induced to forward to you the following case of the same affection, which, if it be considered interesting enough, I beg you will insert in your truly independent periodical. I have the honour to remain, Sir, yours respectfully,

JOHN J. KELSO, M.D.

Lisburn, Sept. 11, 1835.

Miss B., at. 19, is of a delicate make of body, with light brown hair, fair complexion, and of a nervous temperament. Previous to the commencement of her present illness, she enjoyed, for the most part, tolerably good health. On the 21th of December, 1834, I saw her for the first time, and found her in the following condition: She was lying extended on her back, perfectly motionless, with complete deprivation both of consciousness and sensibility; the muscles of the extremities &c. were quite flexible; the respiration about four in the minute, the heaving of the chest being scarcely recognizable; occasionally, a short expiration, with a sigh or a moan, succeeded to a deep and sonorous inspiration. Pulse 60, fluttering and weak; skin rather cold and exsanguaneous. Intense cephalalgia, as evinced by the occasional involuntary application of her hands to the forehead, which she would violently press until they were removed by some of the attendants. Eyelids closed, and on being raised up, the eyeballs are found strongly turned upwards; pupils dilated and fixed. Peculiar placidity of countenance. Catamenia &c. regular. This cataleptic state persisted for about nine hours, terminating in a confused sleep. The prostration at one time was so great that it was thought she would sink, the pulse having become imperceptible, and the respiration for nearly two minutes wholly suspended. Dr. Thomson, who had previously seen the case, had ordered a fetid enema, and leeches to the temples.

27. The catalepsis, which is almost continual, is now announced by the loss of command over the voluntary muscles, the head falling back, the eyes closing, and the other muscles becoming at the same time relaxed. It invades suddenly and insensibly, and on recovering she recollects nothing that has passed during its continuance, nor can she be aroused out of it by the strongest stimuli;

headache relieved by the leeching, but sometimes excruciating; tongue clean; appetite good.

30. The fits to-day are hardly so frequent, or of such long continuance. During the attack she sighs or moans frequently, and, if mild, music will attract for a little her attention. The striking of the clock, too, will occasionally make an impression upon her, the strokes of which she will accurately count. On recovering from the seizure she instantaneously regains possession of all her faculties, and during the intervals between the paroxysms her spirits are good, and she employs herself in reading. Headache teasing, and there is globus hystericus. Restless nights. *Somat Tract. Humuli ʒij, hora somni.*

Jan. 5, 1835. The headache and globus hystericus are peculiarly distressing during their existence, and for an indefinite time after the passing off of the fit. Pain of a neuralgic nature is felt in the course of the infra-orbital nerve, and she frequently experiences tooth-ache, which always aggravates her state. No other alteration.

Feb. 15. On those days on which the fits are fewer they are invariably longer protracted, and *vice versa*. They have assumed a periodical character, invading at one o'clock and at seven p.m., persisting generally at each time for about three hours. During the rest of the day she is completely exempt from their attack. She has been taking the carb. of iron, which has been increased to ʒviij daily, without producing much benefit. It may be remarked that the morning which is ushered in with violent headache, invariably effects an irritability of temper, with a protraction of the fits, and an increased amount of suffering generally during the whole of that day. Appetite defective; bowels preserved relaxed by suitable aperients. Sleep still to be solicited by the anodyne.

27. The fit is announced by the fixing of her eyes on some imaginary object, either on the ceiling or the wall, which she will continue, as it were, attentively examining with a smile or a laugh, pointing to it at the same time with her finger. In this attitude she will remain until recovering from the seizure, when a convulsive tremor ensues, with the effusion of abundance of tears and frequent sighing. To-day the recovery from the fit is announced by a difficulty of obtaining breath, as it were, accompanied with a violent and frequent heaving of the chest, so that the respiration would appear to amount to 90, or more, in the minute. This state persists for three or four minutes, and then passes off in sighing. She has been taking sulphate of quinine, which has been increased to ʒi daily, with but little benefit.

March 27. For the last few days the fits had recurred less frequently, and her general health was improving with her appetite,

from the taking of exercise. To-day, however, she became suddenly and unexpectedly worse. The catalepsy was preceded by a general convulsion, which lasted for nearly an hour. If she happens to be in the erect posture when the convulsive paroxysm invades, she becomes so rigid as to render abortive any attempts to bend her: again, if she be reclining, the flexor muscles of the trunk, by an instantaneous and violent effort, will elevate her into the semi-erect state. There is tenderness in the spinal column generally, but especially acute over the sixth and seventh cervical, the tenth dorsal, which is evidently depressed, and all the lumbar vertebrae. Pressure, if practised on any of those tender parts, excites acute pain and a sense of constriction, as if the body was ligatured by a cord; it invariably excites a fit, or the convulsion terminating in it. It was mentioned to me now that about eight months previously, a tumour, of the size of a fowl's egg, was developed, at about the situation of the depressed vertebra, but disappeared after some time, spontaneously. Intense headache, with feverish excitement. *Hirudines x dolent, pithus dorsi.*

30. The convulsive paroxysm, which is not so furious, is sometimes alternated with jactitation. In some of the violent paroxysms she will commence crying immoderately; the crying being occasionally alternated with violent laughter. Nights disturbed by alarming dreams, rest not being procured, as was wont, by the anodyne. There is general soreness over the surface of the body. Bowels &c. natural.

April 5. The catalepsy very frequent, lasting for about ten minutes, and the convulsion or jactitation which always precedes it, about six minutes. The nights are not exempt now from the fits, which the least mental excitement will produce. The panting respiration frequently recurs, during which the chest and abdomen are alternately elevated, with a remarkable frequency and violence. Spine very tender. *Halent moschi grs. vi, ter die.* To keep the recumbent posture.

May 5. An uncontrollable propensity to straight-forward progressive motion during the existence of the catalepsy. Spine less tender, from repeated leeching, cupping, and blistering. Pulse not affected during the fits.

20. The tendency to straight-forward progressive motion has disappeared. To this has succeeded a rotatory, whirling, round-about motion, which is always executed from right to left. During the fit she will continue, to all appearance, reading, or following any employment she may have been engaged in prior to its occurrence. Much emaciation, with bad appetite.

September 1. The rotatory motion, with the convulsion and jactitation, entirely gave way in the beginning of July. The cata-

lepsy is yielding, and her general health is improving, from a residence, for these last two months, at the sea-shore. I may mention that about a month since she experienced an attack of toothache, which so much aggravated her state as to render the catalepsy almost continual for the then four consecutive days. The tenderness in the spinal column has nearly disappeared, and the displaced vertebra is fast returning to its natural position.

Remarks.—The case just detailed I consider not only interesting but instructive, from its intimate connexion with acute spinal irritation, and the palpable displacement of one of the dorsal vertebrae. Although we find hysterical symptoms frequently, if not invariably, associated with catalepsy,—affections, it may be observed, not very dissimilar in their nature and seat,

it can hardly be supposed for a moment that they originate from an analogous cause. It is pretty generally admitted, that irritation, in which ever a nerve excited, acting on the origin of the spinal nerves, in predisposed habits, is the primary and chief cause of the development of hysteria; but since that affection presents itself so frequently in the absence of every cataleptic symptom, the pathologist must search after some other cause, or series of causes, that operate in producing the affection in question. What has been here advanced, however, does not in the least militate against what must be acknowledged as a fact, in my patient's case, viz. that irritation in the medulla spinalis, or the origin of those nerves issuing from it, excited from whatsoever cause, was an essential link in the chain of causation, for the high degree of tenderness in particular parts of the spinal column, on making the least pressure, so suddenly set up on the 27th of March, from imprudent exercise, with the irritation resulting from the displaced vertebra, which was then detected for the first time, were accompanied by a marked aggravation of the convulsive paroxysm. The intensity of the affection, too, yielded on instituting the appropriate treatment for the removal of the local irritation, which being in great measure effected, the convulsive fits and jactitation, which was occasionally violent, entirely ceased. It is to be regretted that the spinal column was not subjected to an earlier and accurate examination respecting its real state. It must, however, be quite evident, that the irritation or inflammation which led to the slight angular curvature, must have existed for some time, and very probably from the period of the existence of the tumour on or near that place, which was, as reported, about eight months before. But although the displaced bone is fast returning to its appropriate place, and

acute tenderness experienced there and in other parts of the spine has nearly disappeared, the catalepsy still persists. This may arise, I think, as much from the morbid habit established in the system, as from the continuance of the cause which originally called it into existence.

The headache, all along a peculiarly prominent and harassing symptom, may be viewed as sympathetic on the spinal irritation, and the straight-forward and rotatory motions are referable, I conceive, to irritation influencing the origin of more or fewer of those nerves which are subservient to locomotion.

With regard to the treatment of the case, those means which were employed for combating the local irritation in the spinal region were the most beneficial. The internal remedies were not equally efficacious. These were chiefly carbonate of iron, quinine, camphor, ether, and musk; and although several other things were prescribed, she obstinately refused taking any of them.

CASE, FREQUENTLY SIMULATING HYDROPHOBIA.

To the Editor of THE LANCET.

SIR, In the number of THE LANCET published on the 29th of August last, I saw an article entitled "Remarks on Pseudo-Hydrophobia, by Dr. Hare." I must certainly agree with the Doctor in thinking that the case related by Mr. Tonkin in THE LANCET for August 15th, was "one of those mysterious neuralgic diseases which medical men sometimes meet with;" and a case fell under my observation last year which the remark of Dr. Hare brings to my recollection. I remain, Sir, your obedient servant,

J. L. MCCARTHY, M.D.

Macroon, Sept. 11th, 1835.

A young and fine-looking man, a soldier in the 70th Regiment, belonging to a detachment of that corps quartered at Millstreet, about fourteen miles from this place, was sent in here by the apothecary in charge of the troops at Millstreet, for the purpose of being transmitted to head quarters in Cork. Lieutenant Jameson, commanding the detachment of the 70th, which was quartered here, called on me and begged that I would go and see this young man, who he said was reported to him as having hydrophobia.

I accordingly went with Mr. Jameson to the barracks, and found the patient bound down to his bed with sheets twisted round his body, and arms. He was then in

a convulsive fit, struggling violently, howling and barking like a dog. He attempted to bite at everything placed near his mouth, and the slightest blast of cold air, or the sprinkling him with any kind of fluid, aggravated the fit. His respiration was extremely irregular and convulsed, and he frothed considerably at the mouth. At the same time he was, to a great degree, conscious of what was going on, and would, when the spasm permitted, answer questions that were put to him. He complained of great pain in the back of the head, along the spine, and in the epigastric region. The sergeant of the party told me that the fit had now lasted nearly an hour, and that the patient would soon fall asleep, as he was showing signs of faintness. I staid with him about half an hour, when the convulsions gradually abated, and he sank into a deep natural sleep. I then felt his pulse, and found it full, hard, and counting 97. The sergeant who had accompanied him from Millstreet told me that his bowels were most obstinately constipated.

I recommended Mr. White, an apothecary in this town, who had the medical charge of the troops here, to have him bled freely, and to give him a strong bolus of calomel, jalap, camphor, and ginger, to be followed by an emema containing castor oil and oil of turpentine. Mr. White, however, did not think proper to follow my advice, and did nothing for the patient, simply reporting the case to the chief military medical officer in Cork, in order to have the man removed to the General Hospital.

When the patient awoke from his sleep, which had continued for four hours, I again went to see him, and obtained a history of his case. He told me, that when a boy about ten years old, he was bitten in the hand by a dog which was supposed to be mad. The dog was killed immediately afterwards, but it was not properly ascertained whether the animal was really rabid or not. The wound became very sore, and festered. It was cauterized by a surgeon, and then tormented by the application of various ointments, and at last, being ultimately left to nature, healed, and cicatrized in about three weeks. The accident occurred in the month of January, and some time in the following May he was attacked with symptoms so like those of hydrophobia, that the medical man who attended him at once pronounced it to be that disease. He did not recollect any thing of the treatment he then underwent; but in about a week from the commencement of the attack he completely recovered. He had then two of the convulsive fits in the twenty-four hours, and they were, he said, precisely of the character of the one which I saw. He further stated, that the convulsive fit was always preceded by a sense of suffocation, tightness across the chest, a heavy weight at the epigastrium, extreme

difficulty of deglutition, and a feeling of horror at the sight of fluids; but that when the fit went off, he found himself quite well, but exceedingly weak, and able to swallow both fluids and solids, with the same facility as when in a state of health. He was at that time in his 19th year, and he said that he had, since his first illness, experienced an attack of this disease regularly every spring, and also sometimes in the autumn; during the intervals he always enjoyed robust health. His illness was always preceded, for some days, by constipation and irregular digestion, which also accompanied the attacks, and free purging gave him the greatest relief.

He remained here for nearly a week in this state, before he was transmitted to Cork, and the fits were daily getting worse, as no treatment was adopted. I afterwards learned, that being put into the Cork General Military Hospital, he was bled and purged, and perfectly recovered.

I asked this young man why he barked and howled while in the fits, and he told me that he always fancied there was a troop of mad dogs about him, but that in every other respect his mind was unaffected. He said that two medical gentlemen who had attended him in two different attacks, both stated that his case was one of hydrophobia, and was cured by them.

I consider this affection to be one analogous to the hysteria in the case related by Messrs. Tomkins and Varenne, and to have been originally caused by the bite, and the irritable treatment of the sore, afterwards recurring from habit and disorder of the digestive functions, the affection assuming a periodicity in its type.

could with safety pronounce whether a "sickly dog" was capable of producing hydrophobia by its bite or not. And herein consists the difficulty; for it has happened, as most people are aware, that, sometimes, at the period of inflicting a wound which has afterwards proved mortal, the animal has been actually unsuspected; and therefore we may conclude that in the woman whose case has been the subject of controversy, the symptoms having been plainly those which are considered to be normal by the generality of medical authors, the circumstance of the dog not being mad at the period of his death, is no certain proof that the system of the patient was not affected by his virus. Had she died, perhaps the case would not have been considered so doubtful.

When we consider that the slight scratches made by the dog's tooth, appeared inflamed on the 8th of August, after having been completely healed since the 24th of the previous July, it must be acknowledged that there was something more in the wound than is usually met with in simple abrasions of the skin, whether caused by a dog's tooth, a nail, or otherwise; and also when we pass in review the concurrent symptoms, there seems to be some, if not strong reason, in opposition to the opinion of Mr. Youatt, for the assertion that there were decidedly symptoms of hydrophobia in the person attended by Mr. Tomkins and myself. I have the honour to be your obedient servant,

E. G. VARENNE.

Kelvedon, September 17, 1835.

HYDROPHOBIA.

REMARKS BY MR. VARENNE ON THE
ARTICLE BY MR. YOUATT.

To the Editor of THE LANCET.

SIR,—I should feel obliged if you would insert in your valuable pages the following brief remarks, which bear reference to some observations on a case of supposed hydrophobia, contained in your 624th number.

A point of interest, with respect to hydrophobia, rather overlooked by the writer of those observations, remains yet to be examined; and that is, how long before decided symptoms of that disease make their appearance in an animal, is that animal capable of affecting the system of man or of other animals with the disease in question? It may not be impertinent to state, that the symptoms of what is called the latent disease are never so constant, in all cases, that even an experienced and skilful veterinarian

ON THE NATURE OF INFLAMMATION AND IRRITATION.

To the Editor of THE LANCET.

SIR,—In requesting the favour of your allowing the subjoined paper to occupy a space in your Journal, some apology is necessary for adding to the number of attempts to explain the nature of inflammation, the more so, since the present inquiry is far from being complete. It forms merely a link which could not with propriety be excluded from a series which will hereafter compose a work on the treatment of inflammatory and febrile diseases. I am, Sir, yours respectfully,

HENRY SEARLE.

Kennington, Sept. 19, 1835.

In the various descriptions which have been given of the nature of inflammation, so much importance has been ascribed to the changes which have been supposed to take place in the circulation of the blood, that the numerous hypotheses which have

appeared on the subjects have been raised upon the alleged changes. One condition in particular has attracted, and even riveted, the attention of physiologists:—viz. the turgescence of the vessels, occasioned by the augmented columns of blood. Turgescence of the bloodvessels has always been considered the *sine quâ non* of inflammation; the redness, swelling, pain, and even the increased heat, have been generally attributed to the increased quantity of blood in the inflamed part, and its cause has been supposed to be identical with the proximate cause of inflammation. It is therefore not surprising that the grand point of inquiry should have binged upon this turgescence.

The turgescence can arise only from an obstruction, or from an augmented flow, of blood through the vessels; and from the views taken of these two opposite states, have originated the two leading hypotheses with their respective modifications. The former, the doctrine of obstruction, was first broached by Boerhaave, who attributed the accumulation of blood, forming the turgescence, to an *error facti* of some of its particles, which, becoming imparted in vessels too small for their transmission, required an increased action of the heart and arteries to overcome the obstruction. Cullen modified this hypothesis by ascribing the obstruction to the vessels themselves, instead of to the blood, and attributed the proximate cause to "a spasm of the extreme arteries, supporting an increased action in the course of them."

Various modifications of this doctrine of obstructed circulation have since appeared; debility in various degrees, even to atony of the small arteries, has taken the place of spasm, an increased action, however, of the larger arteries being retained as an essential part of the hypothesis.

The other *leading* hypothesis—viz. that the turgescence arises from an augmented flow of blood through the inflamed part, was established by Hunter. There were several reasons for this doctrine obtaining almost universal assent; it was described by teachers as consisting of a simply increased action of the arteries, including those leading to the inflamed part, as well as those engaged in the inflammatory action; the simplicity of this view readily superseded the incompatible notions of an obstruction of an augmented flow of blood coexisting in different parts of the same chain of vessels; surgical facts daily confirmed the idea of an augmented flow of blood through the inflamed part, and the apparent increase of vascularity was an almost positive proof of this being the case. The authority of so careful an investigator of medical science as Hunter was not likely to be much doubted in his own day; various modifications of the hypothesis have how-

ever been since brashed. Hunter's explanation of the action of the arteries cannot be admitted by any one acquainted with physical science; he goes so far as to reverse the order of nature, describing the natural circulation to be accomplished by the active contractions of the arteries, but the circulation concerned in inflammation to be achieved by their active dilatations. This far-fetched explanation of the cause of the turgescence has been very little considered, otherwise it could not have been so well received. Since the microscope has been so much employed in the investigation of the circulation, the doctrine of obstruction has again become prevalent.

On reviewing the different hypotheses respecting the nature of inflammation, one common error presents itself, viz., that of endeavouring to trace all the phenomena of inflammation to a particular state of the circulation; but such a state does not exist. It is true, that on the turgescence of the vessels depends the chief, if not all the external, signs of inflammation, and on this very account it has been the stumbling-block of many distinguished men, who have vainly sought for the cause of the turgescence as the key to the true theory of inflammation.

It is supposed that inflammatory action occurs in the following manner:—That an adequate excitement of the nerves of the part causes certain changes in the circulation of the blood, evinced by the more usual signs—redness, tumefaction, pain, and increased heat, and that this particular state of the circulation is essential to the production of the various morbid effusions, indicating the existence of inflammation.

In order to prove that a preliminary stage of inflammatory action is not essential to these productions, many familiar examples may be given. In cases of scalding, the effusion takes place immediately on the application of the stimulus of heat, as the direct effect of the nervous excitement, and not the effect of an intermediate inflammatory process of the bloodvessels. In irritative fever, as it is called, collections of pus sometimes occur in distant parts of the body without being preceded by redness, throbbing pain, increased heat, or other sign of phlegmonous inflammation; but so soon as these collections produce a certain degree of distention, their existence is indicated to the patient by the uneasiness they create. In the same manner chronic abscesses are often formed without betraying any symptom of arterial irritation.

Although these examples form mere exceptions to the general rule, yet they sufficiently prove that the morbid productions of inflammation do not depend either on an increased action of the arteries, or on any other change in the circulation, but that they are the results of a morbid function of the secreting vessels. It is true that a local

excited action of the arteries mostly precludes the morbid effusions, but it would appear that these are distinctly different effects of the same cause: for, an increased action of the arteries alone, or a morbid function of the secreting vessels alone, or both these effects conjointly, may arise from one and the same cause. The following comparison between irritation and inflammation will tend to elucidate this view of inflammation.

Irritation consists in a simply excited action of the minute arteries, unaccompanied by derangement of their secreting extremities, while

Inflammation appears to consist essentially in functional derangement of the secreting vessels, which, in most instances, is accompanied by an increased action of the arteries.

Simple arterial irritation occurs under a great variety of circumstances. It may be momentary—the most transient and trivial deviation from healthy to higher vascular action is witnessed in the blush occasioned either by mental emotion or gentle friction;—or it may be durable—the erythematous patches or mucous membranes irritated by the contact of vitiated secretions, may exist for years without assuming a strictly inflammatory character.

This simple vascular irritation may be either local or general: it may present itself as a mere erythematous speck, or in the diffused exanthematous form of rubeola, or of scarlatina.

General vascular irritation may occur either in *paroxysms* or in *continuous forms*. The *paroxysms* may be produced by mental emotions, by taking certain stimulant and sudorific medicines, cordials, as wine, spirits &c.; they may be induced by a sudden check to the circulation, such as is occasioned in cold bathing; they are often periodical, as in intermittent and hectic fevers. The *continuous forms* are observed in pyrexia. Many other examples of increased action of the whole arterial system might be given, in which no particular functional derangement of the secreting vessels can be connected with it, so as to constitute inflammation.

Inflammation appears to consist essentially in functional derangement of the secreting vessels, combined, in most instances, with the arterial irritation already described.

According to this definition of inflammation, the morbid action of the secreting vessels is the essential part of the inflammatory process. So inessential, indeed, is arterial irritation to the existence of inflammation, that various changes of structure occasionally take place without any appreciable increased action of the arteries. Most unequivocal results of inflammation are sometimes discovered in the head, chest, and abdomen; such as enlargements of the

lymphatic glands, abscesses, adhesions, tubercles, interstitial depositions, accumulations of lymph, serum, or pus, opacities, indurations, softening, and other organic changes; any of which may take place without a sign being evinced, even to the patient himself, of the existence of the slightest arterial irritation. How incorrect then, and at the same time how delusive, a definition of inflammation is that which limits it to an increased action of the arteries, that arterial irritation often occurring without inflammation, and inflammation sometimes existing without any apparent arterial irritation! Consequently no fixed correspondence is preserved between the supposed cause and the effect, if such a relation can be established between them.

Inflammation distinguished from irritation.—Inflammation is in general more durable than irritation. Inflammation is almost always idiopathic. Irritation is very frequently sympathetic. Inflammation is always local; irritation may be either local or general. Irritation often exists without inflammation, but the latter is usually preceded and accompanied by the former. The same cause, in different degrees, may produce either simple irritation or inflammation. For example: if a portion of the skin be subjected to the influence of friction during a minute or two only, simple arterial irritation will be the result; but if it be subjected to the same agent during fifteen or twenty minutes, inflammation also will take place, and a blister be formed; anger may occasion merely a momentary irritation of the vessels of the brain, or it may produce a decided phrenitis. So any other cause, as heat, may occasion a temporary irritation of the arteries only, or its influence may extend to their secreting extremities, and disorder their function, constituting inflammation. Irritation may be in sympathetic connexion with inflammation. For instance; a suffused redness of the face and neck may coexist with cynanche tonsillaris; or an erythematous patch on the cheek may attend inflammation of a tooth or of the gum on the same side, and various cutaneous irritations may accompany gastro-enteritis, or other internal phlegmasia; but the most extensive and dangerous form of sympathetic irritation, is that which is connected with acute visceral inflammation, and presents itself under the character of inflammatory fever.

Acute inflammation in a part is always accompanied by irritation in the contiguous parts, and these diseased actions sometimes preserve a distinct coexistence in different structures, however intimately connected. For example; the submucous cellular tissue may be the exclusive seat of inflammation, while the mucous membrane itself remains in a state of irritation only, which cannot be explained on the principle that

increased vascular action constitutes inflammation. In this case the submucous tissue, the seat of inflammation, becomes changed in structure,—the mucous membrane, the seat of irritation, continuing in its natural condition. In the same manner the cellular tissue of the liver may become inflamed and thickened, or any kind of deposition may take place into it, the lobules at the same time being in a state of mere irritation or active congestion, and secreting bile natural in quality and quantity.

RESEARCHES INTO THE DISEASES OF CHILDREN,

CONDUCTED ON THE

KNOWN PRINCIPLES OF ANATOMY AND PATHOLOGY.

WE intend to publish at intervals, in the numbers of the present and ensuing volumes of *THE LANCET*, a series of cases illustrative of the most important diseases of children, observed at the *Hôpital des Enfants Malades*, in Paris, the only hospital we believe, in Europe, in which children of from three to fifteen years of age are received. Our reports of these cases will, we expect, be very acceptable to British practitioners, to whom we present them as original communications, drawn up with great care, with a view to recording facts from which important practical rules in the treatment of the diseases of children may be drawn. In mentioning that these cases are expressly reported for publication in our own columns, we do so simply to prevent any erroneous impression which may chance to be created with regard to the authority of reports of foreign cases in an English journal, in consequence of a habit which has prevailed in some quarters, of extracting hospital cases from a Parisian contemporary (the *Lancette Française*) without acknowledgment, — a piracy which has excited much complaint from their author in the French journal.

In accordance with our arrangements we commence the series this week by giving the following case, to which we take the opportunity of attaching the name of its author, a gentleman of extensive acquirements and great research in medicine, and well competent to observe and apply the facts which anatomy and pathology can afford to the therapeutic art.

HOSPITAL OF SICK CHILDREN, PARIS.

INFLAMMATORY CROUP.—TRACHEOTOMY.—CURE OF THE CROUPAL SYMPTOMS.—DEATH FROM CAPILLARY BRONCHITIS ON THE NINTH DAY AFTER THE OPERATION.—AUTOPSY.

ALEXANDER GUYON, a boy four years of age, was received into the hospital under the care of M. GUERSENT on the 2nd of June, 1835. The parents of this child are both healthy, but he himself is in general subject to ill health: his chest is very narrow, and the sternum projects slightly forwards from lateral compression of the chest; the child however does not cough habitually. For the last six or seven days the child has been affected with the symptoms of common catarrh, to which latterly some feverish symptoms were added. He was seen in town, on the morning of the 2nd, by a physician, who did not say any thing about croup, or seem to suspect the existence of this disease: at five o'clock in the evening the interne assures me that his cough was moist, and did not at all present the croupy sound; the voice however was a little harsh and hoarse. The disease declared itself suddenly on the night of the 2nd, and at nine o'clock on the morning of the 3rd, the little patient presented us with the following symptoms:—

The face, which is habitually pale, is now somewhat injected, for the patient has just had a moderate access of suffocation. The access was soon repeated, and lasted for a few minutes, during which the child is very much agitated, tosses about from side to side in the bed, and suffers evidently from obstructed respiration. The latter, in the intervals of the fits, is laborious, abdominal, and accompanied with forced dilatation of the nostrils, forty-four in the minute: a sonorous râle passes in the back of the naris. The child coughs a little, every now and then, for a few seconds at a time, but the cough has not the crowing character remarked in croup; he does not speak, we cannot therefore note the character of the voice. The motion of the child when the access of suffocation comes on is very characteristic: he begins to writhe about in the bed, cries, and endeavours to obtain the upright position, but when taken up and held at the window, the fit very soon goes off. The crachoir (tin spitting-cup) contains a quantity of nearly clear-coloured serous fluid, in which we observed floating a portion of white false membrane about three quarters of an inch long by a quarter of an inch broad. On examining the back of the fauces we find a small patch of the same pseudo-membranous concretion covering the left amygdala. The chest sounds well upon percussion, we think however there is some little matity on the right side above and

posteriorly: at this point we have some soufflé bronchique, in other parts of the chest a râle sibilant. The skin is very moist and warm, pulse small, 140, respiration now 48.

On examining the patient M. GUERSENT pronounced the disease to be croup, and ordered the operation of tracheotomy to be performed without delay. The little patient was carried at once into a neighbouring room, and the operation performed by the interne. The child lost some blood from the division of the veins about the lower edge of the thyroid gland, which seemed to us also to have been divided for a few lines, and before the canula could be introduced into the trachea, a good deal of blood had made its way into this tube, and brought on such a fit of coughing and suffocation that we thought every instant the child would have died under the knife: this state, however, fortunately went off after one or two violent accessess; the canula was introduced, and the patient quickly restored from a condition of the greatest agitation and suffering to comparative calm: in a few minutes after the operation, the pulse, which, counted immediately before, gave more than 140 beats, fell to 116, the respiration descended from 48 to 32, and we left the child enjoying a quiet sleep.

4. When we first saw the patient this morning, he was lying asleep; the face was free from moisture, the skin not very warm: the respiration sufficiently calm, and accompanied with a gentle dilatation of the nostrils, 36; the pulse still small, 152. The child soon awoke, and M. GUERSENT coming in, we learned that the child had coughed a good deal during the night, and passed some large portions of false membrane through the canula. This latter tube now became stuffed with thick mucus, and the child was seized with a fit of suffocation very analogous to those we observed before the operation; the face does not become purplish as then, but the child makes violent efforts to respire; his whole body is bathed in sweat, and at each effort the air, mixed with mucus, hisses through the canula with amazing violence; in a few seconds the canula became pretty free; the respiration was then less difficult, though M. GUERSENT says the breathing is almost as oppressed now as it was before the operation. The canula was now cleaned with a morsel of sponge on a bit of whalebone; this caused some agitation, and the pulse rose to 156, respiration 44: a great quantity of greenish mucus, mixed with little or no air, is driven through the tube at each expiration; the child is not very weak, for he stands up in bed without support. Skin moist, not very hot. The crachoir contains several portions of false membrane expectorated during the night; one of which is at least two inches long. *Decoc. Malæ* for

drink; *Solution of Gum* with *Ox. Antimonii*; simple lavement; diet.

5. The second day after the operation was passed nearly in the same state as the former; the respiration, however, became somewhat less embarrassed; the patient discharged from time to time through the canula complete tubes of false membrane, as if derived from the second bronchial division. *Decoc. Malæ*; *Solution of Gum* with *Oxyd. Ant.* xv gr.; simple lavement.

6. The patient looks much more calm to-day than yesterday or the day before; his respiration is also much less laborious, is regular, 38, a few minutes after the canula was cleaned; the patient passed several hours last night in a state of perfect calm; at each expiration a small quantity of greenish mucus is driven as far as the orifice of the tube, but not forcibly beyond it; the appearance of the wound, which is about two inches and a half long, is good, but the skin is somewhat retracted from the edges, and leaves the subcutaneous tissue bare; the child had a fit of coughing during the visit, which brought away some false membrane; the fit was slight, continued only two or three seconds, and did not give rise to any coloration of the face or mouth; however, we may remark that to a non-medical person or parent &c., the child would have appeared to suffer excessively, from the circumstance of his making all the motions which accompany cough in the ordinary state without opening his mouth, or of course producing any sound whatever; the skin is moderately warm, moist, and in some parts covered with sweat; the skin of the forehead is much warmer than that of the face, but not more so than that of the hands or the rest of the body; pulse 144; two stools during the night; in respiration the lips do not move, but we observe a curious physiological phenomenon which we did not notice before, and which, as far as we know, has not been remarked in other histories of this operation. The nostrils move, evidently as if the patient respired through the mouth and nose, but on close examination we find this motion, though pretty regular, is not exactly that of respiration, nor corresponds exactly with each elevation of the chest; the dilatation, or, to give a better idea of the motion, the elevation of the nares, corresponds pretty nearly to each inspiration, but on the whole is slower, and every now and then the nares when drawn up make two or three short fluttering inspiratory movements and then subside; for the last two days the respiratory sound has been obscure at the summit of the right lung. *Decoc. Malæ*; *Sirup of Gum*; *Sol. Gom.*; *wie's Oxyd. Antim.* gr. xvi; milk and water.

7. To-day the child is evidently much relieved; he is now a little gay, and even played for some time in bed yesterday evening, when he was very calm; the pulse

early this morning was 120 to 124; is now 28; the respiration 32 to 36; the patient has had no fit of coughing this morning; and his respiration is now sufficiently free; he passed some small fragments of false membrane last night through the canula; this morning he ate half a biscuit with some appetite; the skin is moist and very slightly warm; there is still some dulness of sound and absence of vesicular respiration at the summit of the right lung. Same remedies; *Opid. Antimon.* xviii gr.

8. The fits of suffocation now no longer exist, but the child had a long and violent fit of coughing during the visit; the canula does not discharge much mucus, and no new false membranes have been passed; the patient is now very feverish; skin burning hot; pulse 144 (this morning at one o'clock it was only 120 to 128); great thirst; respiration not much oppressed, 48; the nostrils exhibit the same motions as yesterday, corresponding very nearly with expiration; no air whatever passed through the mouth or nose. M. GUYER observed that he feared the child was now evidently affected with another disease than that for which the operation was performed, and would die of his croup. *Decoct. Maltæ*; *Op. Antim.* xviii gr.; lavement; milk.

9. The child does not cough much,—only three or four times in the course of the day; the child looks much better than before, and lies quite quietly in his bed; little appetite; pulse now 140, was only 116 this morning (perhaps from irritation caused by pumping out the canula in the trachea); the child was not very thirsty during the night; the respiration not laborious, is irregular, 48; skin moist and very warm, as before; he has not expectorated any false membrane since; a greenish mucus is still discharged from the canula, but after it was cleared out with a sponge two or three times, we observed that the mucus expectorated became rosy; the patient has eaten some currant jelly with great relish. *Opide Antimon.* xviii gr.; currant jelly.

10. Seventh day after the operation. The child lies perfectly quiet in bed, and presents a strong contrast to the agitated state in which we found him on the first day of his disease; the respiration, though a little quick (38) and irregular, is not difficult. The canula was stopped this morning for an hour; he bore this very well, and the nurse says his respiration immediately became more slow and easy. The cough has much diminished, the patient now only begins to expectorate some mucus; is less febrile; skin still moist, but excessively hot; pulse sharp, pretty strong, 132; face has lost all appearance of agitation; not very pale; the child eats a little bread and has some appetite; two stools, one of which was passed in bed, but it appears that he did not dirty his bed

at home. The inspiratory motions of the nostril are now much less perceptible; the wound looks well, does not suppurate; the cervical and submaxillary glands are not tumefied. Wine and water; solution of gum; broth.

11. The patient has coughed very little during the night; skin not so warm as yesterday; pulse 120; respiration 48; on auscultation we hear some dry crepitating rale in the right lung posteriorly; the canula has been stopped several times since yesterday, and the interné again assures us that the respiration becomes more slow during that time; skin not very warm. Wine and water; *Op. Antim.* gr. xij; chicken broth.

12. The canula was removed yesterday, and has not been replaced since; the cough is not distressing or frequent; however, the respiration has been embarrassed from time to time, especially during last night. It is now a little difficult, 48; pulse small and very rapid, 136; skin rather cool. The child has had a good deal of diarrhœa; five liquid stools; tongue white, but moist and not foul. From this time the child began to sink rapidly; the respiration became more difficult, and he died without convulsions during the night.

Autopsy at ten o'clock on the 13th of June.

Cavity of the Chest.—The left lung looks healthy externally; the right lung is of a mottled red colour in front, and adheres to the parietes of the chest, anteriorly and laterally, by a pretty extensive false membrane. There is no effusion into the cavity of the chest. The trachea when opened does not exhibit any trace of false membrane; there is no inflammation immediately about the edges of the divided rings, but about two inches lower down than the inferior angle of the incision, there is some irregular capillary injection, with two or three points of ecchymosis in the lining membrane; there is also some ecchymosis above the wound, with some capillary injection round it. The whole of the bronchi, from origin to termination, are deeply injected, and when divided near the surface of the lung they discharge a mucous-purulent fluid, and seem somewhat dilated; no false membrane in any part of trachea or bronchi. On again examining the trachea we perceive on the right side of the incision that the mucous membrane is of a rosy colour, for about one inch in length by a half in breadth: the membrane then exhibits a yellow colour, as if it had been bathed in pus for some space down, and then the membrane again becomes injected about an inch above the division of the bronchi. The whole inner surface of the trachea is rough to the feel, and looks here and there as if the mucous membrane had been removed, but there is no trace whatever of ulceration. When the summit

of the right lung is divided, it presents a gray-yellow colour, from the infiltration of tubercular matter; the appearance is different from that of gray hepatization; the tissue is here soft, and yields under the finger with readiness; on the right lung also, about a quarter of an inch from the surface of the lung, and situate near the lower edge of the part adherent to the costal surface, we find a tubercle, in a crude state, about as large as a five-sous piece; and near the summit a number of smaller tubercles. Here some points of the lung have a solid feel, and are much engorged, but do not give way under the finger, or present the dark colour of an hepatized lung. Inferiorly in this same right lung the small bronchial tubes are excessively injected with a deep-red capillary injection, and the tubes, when the lung is squeezed, give out a quantity of bloody mucous fluid, mixed here and there with some pus from certain of the bronchi. Between the upper and middle lobes of the right lung behind, we find some false membrane, which partially unites them together, and also to the side of the chest. The whole of the base presents the same appearance as the upper part, except that it is somewhat more dark than the gray-yellow colour above, and the tubercles are more soft. At one point, about four inches in extent, the substance of the lung round the tubercles is very red, and excessively solid; it does not yield under the finger, but tears readily, and sinks rapidly in water. The left lung is in general healthy, i. e. free from appearance of pneumonia. At the summit, particularly, there is a great number of small crude tubercles, but no appearance of inflammation of the pulmonary tissue; the base of the left lung is much engorged when cut into, but not solid, or impervious to air.

Here and there some of the tubercles are softened, and discharged their pus into the bronchi when we pressed the mass of lung.

The amygdalæ are a little hard, but not discoloured, or covered with false membrane; nor do we find any in the pharynx; the œsophagus is pale internally, but the mucous membrane lining the back of the larynx externally, i. e. the crico-arytenoidal surface, is very much injected, purplish, and wrinkled like a piece of half-dried parchment. No injection or appearance of false membrane about the larynx or cordæ vocales.

The stomach is empty; near the grand cul-de-sac the membrane is pale and somewhat softened, but presents no trace of inflammation. There was nothing worthy of detailing in the viscera of the abdomen or head.

RESEARCHES INTO THE DISEASES OF CHILDREN,

CONDUCTED ON THE

KNOWN PRINCIPLES OF ANATOMY AND
PATHOLOGY.

HOPITAL DES ENFANS MALADES,
PARIS.

CROUP.

IN France the name of "croup" is confined exclusively to inflammation of the larynx and trachea, accompanied by a pseudo-membranous exudation. During the last five years this affection had been extremely rare at the *Hopital des Enfants*, and not more than three or four cases were observed; but it presented itself much more frequently in the course of the year 1835, during which we have observed no less than ten cases, affecting children from two to six years of age. The treatment employed in the majority of these cases consisted in the use of emetics, purgatives, local blood-letting, and cutaneous revulsives (blisters to the pole or front of the neck, to the superior or inferior extremities, &c.) The operation of tracheotomy was performed four times, and always accompanied by a momentary improvement in the symptoms, but the cases have nevertheless been fatal; in two patients death took place about thirty-six hours after the operation, once in forty-eight hours, and in the fourth, whose history we have already published (see p. 29), the fatal termination did not arrive before a lapse of eight days. In some of the cases above enumerated the diagnosis was attended with considerable difficulty: thus, in one case, we have seen a physician attached to the hospital mistake a real croup for an *edematous angina* (*edema glottidis*); we

have also seen a case of simple inflammation of the larynx and trachea mistaken for croup; we shall report the latter case after having detailed one which did not present the slightest doubt, from the well-marked symptoms by which it was accompanied.

CASE.—Child five years old. Cough and hoarseness at the commencement; emetic; amelioration for two days; then alteration of the timbre of the voice; croupal cough; expectoration of false membrane; two applications of leeches to the neck; frequent emetics. Death on the seventh day; membranous concretion in the larynx and trachea; puriform mucosities in the bronchi.

Delorme Antoinette, a girl five years of age, of a good constitution, was seized on the 21st of August, together with one of her sisters aged two years, with cough and hoarseness, and dyspnoea. A physician being called in, prescribed an emetic for both the children; the accidents increased rapidly in the case of the younger child, who died with the symptoms of croup in three days. The elder sister felt some relief from the effects of the emetic, which persisted on the 26th and 27th, but on the following night she was seized with a frightful access of dyspnoea, which determined the parents to transport her to the hospital. On the patient's arrival she was immediately given an emetic, which produced copious vomiting, accompanied by efforts to cough; in the midst of the matter thrown up was found a morsel of false membrane, organized, and as large as the thumb nail.

29. At the visit in the morning we found the child lying on the right side; the head thrown back; the face pale; the neck tender; the cervical glands on the left side engorged; pseudo-membranous concretion on the amygdala of the same side; respiration siffilante, twenty-eight per minute; fit of a hoarse dry cough; alteration of the voice, which is weak and barking; pulse accelerated; skin hot; intelligence perfect.

Ten leeches along the centre of the neck under the chin.

R. *Tart. Antimon. Polass.* gr. j.; *Syrup. Ipecacuan.* ℥j. *Chymel Scyllæ* ℥ss. To be taken in three portions. *Tisan de Mauve*; *diète*.

The patient appeared to have been much weakened by the application of the leeches. The two first portions of the emetic draught were given, with an interval of a few hours; these produced some vomiting, and towards evening the child had several accesses of suffocation; the pulse rose to 160.

30. The child's state seems a little improved, she answers the questions addressed to her, asks for something to eat, and says she feels no pain anywhere. The timbre of the voice is still strong, and the respiration more sonorous than yesterday; cough croupy; pulse 120; respiration 30; tongue moist; the child has not been to stool for the last two days. Purgative lavement; four leeches to the neck; emetics; sinapisms to the lower extremities; milk. During the day the child was seized, from time to time, with fits of suffocation, which on the 31st were repeated almost without interruption, from five o'clock in the morning to nine o'clock, when the child died.

Body examined twenty-six hours after death.

General appearance of fat; skin pale; no cadaveric rigidity; injection of the vessels on the surface of the brain; gray substance natural; white substance somewhat injected; ventricles contain no fluid; the amygdalæ, the pharynx, and the epiglottis, do not present any appearance of a pseudo-membranous exudation, nor is the mucous membrane lining those parts of a colour remarkably red. The ventricles of the larynx are filled with a muco-purulent fluid, and below them we find the commencement of a membranous concretion, which extends as far down as the bifurcation of the bronchi; it is about half a line thick; the subjacent mucous membrane is red and thickened; the bronchi contain some purulent mucosities, but do not present any trace of false membrane. The mucous membrane of the stomach and intestinal canal is free from all injection or membranous concretion. However, several of the glandulæ solitariae are developed in a very remarkable degree, without being injected. Nothing particular in the other viscera.

The symptoms by which this case was characterized were very clearly marked and evident—viz. alteration of the voice, croupal cough, respiration sibilant, false membranes on the amygdalæ, and also an expectoration of organized membranes from the trachea. The greater part of these symptoms were absent in the following case, which was mistaken for croup:—

CASE 2.—*Simple Laryngo-Tracheitis mistaken for Pseudo-membranous Laryngitis.*—Child three years old; pain in the throat after exposure to cold; then cough; hoarseness; dyspnoea; sonorous respiration; access of suffocation. Death; redness of the lower part of the larynx, trachea, and bronchi; no false membrane.

Garope Adele, three years of age, a child remarkably fat and well-looking; never had any previous illness, except a mild small-pox in her infancy; had been three days ill when she was brought to the hospital on the 10th of August last. According to the account given by the mother, it would appear that this young child, after having amused herself all day on the 8th on the banks of the river, was seized with hoarseness and cough in the evening on returning home. These symptoms persisted the following day; the appetite seemed then diminished, but on the night of the 9th the infant was seized with fits of suffocation, which made the parent believe she would suffocate every moment. The fits did not continue the next morning, but as the cough, hoarseness of voice, and dyspnoea, increased, the patient was brought to M. TROUSSEAU, who declared that she was affected with croup, and immediately sent her to the Hôpital des Enfants Malades, with a written invitation to the person on duty to practise as soon as possible the operation of tracheotomy; he also obligingly sent a box of instruments, lest the interne might not be furnished with everything necessary for the operation.

Immediately after the child's arrival at the hospital, the back of the mouth and throat were examined, and nothing was observed except some redness and tumefaction of the amygdalæ. The hoarseness of the voice and cough showed clearly enough that the inflammation had extended to the air-passages; but there was, at the same time, every reason to believe that the inflammation of the larynx and trachea was of the same nature as that observed in the throat; ten leeches were accordingly applied on the sides of the larynx. A simple lavement given, and mustard poultices applied to the lower extremities. The child slept very profoundly during a great part of this night.

August 11. We saw the child to-day for the first time; the face was moderately coloured; the position of the child in bed varied; the intelligence was perfect; she spoke to her parents who visited her, and intreated to be taken home. The voice and cough were hoarse; the inspiration sonorous, but not sibilant, ~~thirsting in a minute~~; deglutition easy; the redness and tumefaction of the amygdalæ are somewhat diminished; skin warm; pulse accelerated.

not count it, from the restlessness of the child.

R. *Tartar. Antim. et Potass.* gr. i; *Ipecacuan.* ʒss in four parts; mustard poultices to legs. *Diete.*

Momentary calm after the vomiting. In the evening a few fits of dry hoarse coughing, and dyspnoea.

12. Face is more coloured; the child affects the upright posture; the inspiration continues sonorous, and is heard at a good distance from the child; the voice is hoarse, but does not resemble the voice of croup; the cough at times resembles the barking of a small dog; when asked where she suffers, the patient sometimes says in the neck, sometimes in the belly; there is no appearance of false membrane in the back of the throat; the redness of the palate and amygdalæ are much diminished.

Sulphur, sublimed and washed, ʒj; *Sugar* ʒi; in six doses. Same emetic as yesterday, to inspire the vapour of sulphuric ether.

This day was passed quietly, but towards evening agitation and dyspnoea.

13. The cough, voice, and respiration, present the same characters as during the former days; the anxiety of the patient is somewhat increased; the sulphur and emetic powder were continued, and a large blister was applied to the anterior and superior surface of the thorax; the neck was rubbed with an ammoniacal lotion; during the day abundant diarrhoea.

14. At the moment of the visit the patient was in a profound sleep; on awaking she made some efforts at coughing; the cough is more moist than yesterday, and is followed by some expectoration of a matter produced in the œsophagus. We observe some little anxiety, some grinding of the teeth, but nothing announces an approaching termination of the disease. The stools are extremely frequent, and the matter passed is clear, like water. The abdomen is painful to pressure; nothing remarkable took place in the course of the day or night, but at seven o'clock in the morning the child was suddenly seized with a fit of suffocation, which carried her off before anything could be done for her relief.

Body examined twenty-four hours after death.

Exterior Habit.—Considerable embonpoint; purplish tint of posterior part of trunk, and of the upper part of chest and neck. The dissection was commenced by dividing the lower jaw; the cavity of the mouth was then examined with care, and no alteration discovered. The amygdalæ were as large as a small filbert; they do not exhibit any inflammatory injection either

externally or internally; the velum palati healthy; pharynx of a violet colour; the mucous membrane of the epiglottis and superior part of the larynx are pale and not thickened. We do not observe any trace of false membrane or ulceration. The inferior moiety of the larynx and the trachea are red; their lining membrane thickened; the same lesion is found in the bronchial tubes of large caliber, which, moreover, contain some purulent mucosities. The left lung adheres at the summit to the pleura costalis for the extent of about a twenty-sous piece, and at the level of this adhesion the pulmonary tissue contains a cretaceous tubercle of the size of a pea; the remainder of the superior lobe is soft and crepitant; the inferior lobe is slightly engorged; right lung healthy; heart and pericardium free from alteration.

Abdomen.—The mucous membrane of the stomach, of a white rosy tint, presents everywhere a good consistence; the small intestines show here and there some patches of injection, and contain a single lumbricus; in the colon, deep red injection, disposed in striae very closely applied to each other, with ramolissement of the mucous membrane. Nothing worthy of notice in the other viscera.

From this latter fact, to which we might add several other analogous ones, we think ourselves justified in concluding,—

1st. That the diagnosis of croup occasionally presents many difficulties at the bedside of the patient.

2nd. That we ought not to decide on performing the operation of tracheotomy without a full and careful examination of all the symptoms; for this operation is, to say the least, useless in cases where no false membrane exists.

3rd. That simple inflammation of the trachea and larynx may give rise to fits of suffocation, which resemble closely enough those observed in the pseudo-membranous laryngitis or true croup.

We may observe, in conclusion, that in the case just reported, the error of diagnosis was not without prejudice to the patient; for if the physician, instead of giving repeated emetics, which perhaps gave rise to the inflammatory condition of the colon observed after death, had repeated the sanguineous emissions, under whose influence the inflammation of the throat was dissipated, he might also have been fortunate enough to subdue the analogous inflammation of the air-tubes.

MENINGITIS.

Inflammation of the membranes of the brain is a disease much more common at the Children's Hospital than at any of those consecrated to the reception of adults. This affection, considered under the double relation of its march and anatomical character, presents itself in infancy under two forms that are sufficiently distinct. In the first, the inflammation of the cerebral membranes is, in most cases, *primitive and acute*; is developed under the influence of *appreciable causes* (such as blows on the head &c.); passes rapidly through its different stages; and, when death supervenes, leaves, as pathological characters, serous, sero-purulent, or sero-albuminous effusions in the pia-mater, ventricles, or (*much more rarely*) in the grand cavity of the arachnoid.

In the second, which is so much more frequent at the French Hospital for Children, that it may be regarded as the type of the disease, the affection commences under a *chronic* form, and does not become *acute* until a period more or less near the fatal termination; but when the *acute* stage commences, both forms exhibit symptoms so analogous as not to be distinguished by any means that we as yet possess. This form attacks principally scrofulous patients, and presents for anatomical characters, the existence of whitish or yellow-white, tubercular granulations, varying in size from a millet-seed to that of a rape-seed. These granulations are always found in the pia-mater, where they are sometimes disseminated, sometimes conglomerated, so as to form spots of more or less magnitude, which compress the cerebral substance, and are frequently united with it in a very close manner.

We would denominate the first form, *simple acute meningitis*, and would consecrate to the latter a new term (which sufficiently designates its most essential character), *tubercular meningitis*, or, in popular language, *scrofulous hydrocephalus*.

The two following cases offer examples of the first of these forms. In a succeeding Number we shall give examples of the second, or tubercular disease:—

CASE 1. — ACUTE MENINGITIS OF THE CONVEXITY. — Patient aged six years; headache; general malaise; delirium; afterwards convulsions; loss of speech; stupor; coma; local blood-letting; blister to the

neck. Death on the 16th day of the disease; opacity and thickening of the arachnoid on the convexity of the brain; serous infiltration of the pia-mater, sufficiently abundant to distend the convulsions.

Adelaide Baldy, six years of age, of a feeble constitution, after having passed the whole of the 7th of June exposed to the rays of a burning sun, returned home K. the evening with headache, and pains in the limbs, which persisted on the 8th and 9th. During the night she was unable to sleep, was agitated, and had some delirium. On the 10th some convulsive movements appeared, with trismus, strabismus, and grinding of the teeth. The convulsive symptoms ceased after the expiration of a few hours, and returned again two days afterwards. From this time up to the 17th, the day of her reception into the hospital, loss of speech, stupor, constipation; no bilious vomiting; the patient merely threw up some spoonfuls of tisan. On the 9th, some leeches were applied to the epigastrium; and on the 12th, a blister between the shoulders: the child had also some refrigerating draughts, and simple enemata, and sinapisms had been placed daily on the lower extremities.

June 17th (10th day of the disease). The child presented the following symptoms:—Decubitus dorsal; no renversement of the head backwards; face full; eyelids half open, pupils moderately dilated and moveable; no strabismus; sight preserved. The patient is in a state of stupor, and does not answer any question put to her; shows her tongue when bid, and then falls again into a state of stupor; sensibility of the skin is dulled, but equal on both sides of the body; automatic movements of the left arm, which the patient carries constantly to the nose; the other members are numb; grinding of the teeth from time to time; the tongue is moist, and covered with a grayish coat; deglutition easy; no vomiting; abdomen indolent; no stool for the last twenty-four hours; pulse 108; respiration 30.

Emulcent decoct.; eight leeches, two to each temple, and two behind each ear; sinapisms to the feet; frictions with acetic ether on the limbs.

During the day constant stupor; the patient does not speak a single word; passes her urine involuntarily.

18. The stupor is less marked; the child answers in monosyllables to some of the questions put to her; makes an effort to show her tongue, but is unable; no convulsive movement; no paralysis; pulse 120; inspiration 36; dry cough from time to time.

Continue remedies, without the leeches.

19. No remarkable change in the symptoms.

20. No answer to questions addressed. low groans from time to time; patient

out her tongue, which is dry, and presents some aphthæ on the surface; some diarrhœa has set in, and the abdomen is painful to pressure; pulse still 120; face very dull. To day the appearance of the patient, and the symptoms which she presents, are very much those of a child labouring under typhus fever.

- *Frictions with Camphor Oil on abdomen—on the limbs with Acetic Ether; teaspoonful of Sulphuric Ether internally.*

22. The diarrhœa has ceased, and the stupor has become more deep. Some convulsive movements of the face; no acute cries (called *hydrocephalic* in France); no delirium; the child sighs from time to time; pulse 116. *Blisters to the lower extremities.*

23. At eight o'clock, general convulsions; at nine o'clock, permanent contraction of the right arm, which is demiflexed; carpology in the left wrist; inferior extremities in a state of relaxation; mouth deviated to the left side; pupils dilated and oscillant; strabismus; trismus; two involuntary deflections since the visit; pulse 130; respiration 30.

Three Leeches behind each ear; Blister to the neck.

After the application of the leeches, general convulsions set in; the trismus was so complete, that a single spoonful of liquid could not be introduced into the mouth. Death at six o'clock p.m.

Body examined thirty-six hours after death.

Skull well formed; dura-mater healthy; opacity and milky colour of the arachnoid which lines the convex surface of the hemispheres; under this membrane we find a quantity of troubled serum, sufficiently abundant to form a layer, some lines in thickness, between the membranes and cerebral substance; the quantity of this serosity was so great as to distend the anfractuosités, and even separate the convolutions from one another. The arachnoid, which is thickened, may be detached in layers from one to two inches long, and the pia-mater is not adherent to the cerebral substance; in the parts in contact with the liquid the substance is pale, and seems to have undergone a kind of maceration. The cortical substance is pale and not firm; the fluid effused under the membranes is more abundant on the left side than on the right, and posteriorly more than anteriorly. The membranes lining the base of the skull do not present any alteration. The ventricles contain only a spoonful of clear serum; the central portions of the brain preserve their normal colour and consistence. The rest of the brain and cerebellum is healthy.

• *Brain.*—Old adhesions between the right

lung and the pleura costalis; the lung is a rosy colour externally, soft and crepitant; does not contain a single tubercle. Bronchial glands, heart, and pericardium, healthy.

Abdomen.—The stomach presents some small red bands parallel to its great curve; the rest of the mucous membrane is pale. The portion which lines the great curvature is in contact with a fluid resembling wine- lees in colour, of an acid smell, and is softened; intestinal mucous membrane is pale, and of the natural consistence. The glandule agminate and solitarie are scarcely apparent. The mesenteric ganglia are healthy.

CASE 2.—ACUTE MENINGITIS OF THE BASE OF THE BRAIN, WITH EFFUSION INTO THE VENTRICLES, AND SOFTENING OF THE CENTRAL PARTS.

(The "*Acute Hydrocephalus*" of Abercrombie.)

Male, three years. After some days of malaise, intense headache, with bilious vomiting for four days; convulsive movements of the muscles of the face; somnolence; sighing respiration; coma; reversionment of the head backwards. Death the fifteenth day; sero-purulent infiltration of the pia-mater at the base of the brain. Effusion into the ventricles; softening of the central parts.

Auguste Colson, three years of age, having the skull and thorax malformed, exhibited for a few days malaise, dulness, and a disinclination for movement; when on the 29th of August last, without any known cause, he was seized with very severe headache and bilious vomitings. These symptoms persisted for four days. On the 31st, some convulsive motion of the muscles of the face and limbs; obstinate constipation for the first three days. No active treatment pursued.

On being carried to the hospital, the 1st of September 1835, we observed the following symptoms at the visit of the 2nd.

Child is in a demi-somnolent state, interrupted by low cries now and then; face alternately red and pale; eyelids closed; eyeballs prominent, sensible to the light; pupils seem moderately dilated; senses of seeing and hearing intact; does not answer when spoken to; sensibility of the skin is greatly exaggerated; the least touch makes the child cry out; equally so at both sides of the body; no stiffness or paralysis of the limbs; the left eyelid contracts strongly when we endeavour to examine the eyeball; the other opens with the greatest ease, as if it were paralysed; pulse slow and intermittent, 64; respiration unequal, mixed with sighs, 36; skin moderately warm; tongue natural; one copious vomiting this morning; constipation persists; abdomen supple, is very sensitive to the touch; emission of urine involuntary.

M. GUERRET diagnosed a meningitis.

gits of the base of the brain, and prescribed a large blister to the head, a laxative enema, and an emulcent drink.

3. The blister has acted with sufficient energy; the pulse continues slow and intermittent, 56; the respiration is somewhat more accelerated than yesterday, 40; the cerebral symptoms noted yesterday persist, and we now notice that the left side of the face is much less developed than the right, as if from retraction of its muscles; same condition of muscles of eyelids as yesterday; no strabismus; constipation persists in spite of the enema. The child appears less cross than yesterday.

Oxymel; Mustard Foot-bath; Purgative Enema; keep open the Blister.

4. The face colours brightly whenever the child is excited; the drowsy state persists; machonnement now visible; no convulsion or paralysis of the limbs; same state of eyelids as before; and we now find that the right cheek is less sensible than the left, and that the right pupil is a little more dilated than the left; no acute cries; pulse is less irregular than yesterday, 72; respiration unequal, 51; the abdomen still very sensible to pressure; the right arm is less sensible than the left; legs equally so. Three stools produced by the enema; the skin is now very warm, almost burning hot. In the evening an exacerbation; pulse 116; skin much more warm than in the morning of the 3rd.

5. The child is not much assoupi, as during the former days; does not evince the same sensibility when touched; abdomen not so tender as before; he sighs from time to time; skin not so warm as yesterday; pulse 112, very irregular; respiration very unequal, 32 to 36; one stool; same alternations of flushing and paleness; general symptoms the same as yesterday. In evening at four o'clock, a slight exacerbation, which lasted till five o'clock. *Continue remedies.*

6. To-day the child is able to sit up in bed without support, and there was but little stupor during the night; the left cheek is now very much flushed, the other one pale; the abdomen is still slightly tender; two liquid yellow stools; pulse varies from 112 to 124, is regular; respiration quick, regular, 52; skin warm; pupils moderately dilated; we still observe the peculiar sighing from time to time.

Oxymel; simple Enema; Foot-bath; suppuration to be kept up. Diet.

7. Child lies quiet in bed; eyelids wide open; very little stupor; same alternate flushing of the left cheek only; same contraction of left, and complete relaxation of right eyelid; skin warm; pulse regular, 106; right cheek is less sensible than the left when we pinch them with the nails;

right arm seems relaxed, for when we raise it up, it drops down deadily on the side; the angle of the mouth seems a little prolonged towards the left side; no convulsive motions or cries.

Oxymel; Calomel, gr. iv; Purgative Enema if required. Diet.

9. One small stool after the enema; pulse regular, 104; respiration from 34 to 36; thirst; but little change since yesterday; skin warm; not much stupor; same state of eyelids as before; no vomiting since the first one; no convulsive movement; no rigidity or relaxation of the limbs.

Oxymel; Calomel gr. vi; Purgative Enema if necessary.

Immediately beneath the above notes (which are here much curtailed), we find the following observations in our *portefeuille*:—

"If we had seen this child to-day for the first time, and had not known the history of the case, or observed the symptoms and their march very closely, we should have found it extremely difficult to form a diagnosis. The stupor or sleepiness peculiar to meningitis was now barely perceptible; the pulse and respiration had now become regular, and very nearly natural; they were not *slow*; in fact there was no symptom of cerebral disease to be observed, except the constipation, the difference, so well marked, of contractility between the two eyelids, and the difference in bulk between the two sides of the face, which latter symptom, besides, might very easily have escaped notice, as it was not striking. We confess the appearance and state of the child to-day have much staggered us; however, from a consideration of what has preceded, we find ourselves compelled to conclude, that he *ought* to have meningitis, and that in consequence the case will be fatal."

9. No cries during the night; no vomiting; no stool. When we came into the ward we found the child sitting up in the bed, without any support, and presenting a sufficiently natural appearance. The face is pale; no flushing now observed; no convulsive motion of face or eyes; some grinding of the teeth; skin cool; pulse small, sharp, regular, and equal, 134; the right arm has to-day recovered its motion,—on the contrary it feels a little stiff; child still sighs occasionally; respiration quite regular, 32; thirst; deglutition is quite easy; abdomen tender to pressure; no phenomenon of motility, or change in sensibility of limbs.

Oxymel; Calomel gr. viii; Purgative Enema.

10. To-day is a little sleepier, but not so much so as in the first days; two stools; no cries; face pale; no change of colour remains for last two days; same

wasn; pulse regular, 120; respiration quiet and regular, 36; some contractility of left orbicularis muscle, which prevents us from examining the state of the pupil; right one, though now slightly contractile, is easily opened; no contraction or relaxation of extremities, or rigidity of trunk; abdomen neither ballonne nor retracted, tender.

- *Oxymel*; *Colomet* gr. ix; a little rice. At three o'clock p.m. a slight exacerbation.

11. Stupor; a little sighing from time to time; face pale; no change in its colour; both orbicular muscles to-day contract most powerfully when we attempt to open the eyelids; pupils very slightly dilated; skin cool; pulse very small, 130 to 140; respiration very irregular, 22; right arm now cannot be flexed easily, and left arm cannot be extended; three stools; abdomen tender. *Remedies as before.*

12. During the day, yesterday, the child became quite stiff at different times; during the day also he frequently carried his hand to the head, but uttered no complaint; now lies quietly on back; lids open; eyes rolling upwards; upper extremities stiff, as also the right lower one; pupils dilated, immovable; conjunctivæ injected; pulse very small, 140; respiration 36; face very pale; skin cool.

Death at five o'clock a.m. on the 13th.

Body examined on the 14th at nine o'clock.

The *spinal marrow*, which was the part first examined, presents a natural appearance. Nothing observable except some injection of the membranes at the inferior part.

Brain examined from below upwards. The membranes covering the right side of base not more injected than natural; on the left side the whole blunt end of the middle lobe, immediately behind the fissure of Sylvius, presents, for the space of two to three inches long by a half broad, a straw-coloured infiltration under the arachnoid; here the membranes are adherent and thickened, but the membranes themselves here, or in the surrounding parts, do not exhibit the red vascular appearance of recent inflammation.

On the upper surface of the brain the difference between the appearance of the two hemispheres was most remarkable; on the right side the injection of the vessels of the pia-mater was moderate, perhaps a little more than natural; on the left side the whole surface of the hemisphere is covered with fine vessels, and between the convolutions the trunks ascending from the base of the brain are excessively gorged with dark blood; here and there we observe some rosy spots under the arachnoid, as if from the infiltration of the serum. The medullary substance of the left side is also

much more injected than that of the right. We do not observe any granulations in the pia-mater.

The ventricles are considerably developed posteriorly, and contain about three ounces of clear serum. The inferior surface of the corpus callosum, the fornix, septum lucidum, &c., are very much softened, and reduced to a pulp; the floor of the ventricles is of a pinkish hue. Cerebellum and medulla oblongata healthy.

Lungs healthy—merely some tubercular matter in the bronchial glands.

Abdomen not examined.

In this last case a blister to the head was the only treatment employed; but we are not to conclude that M. Guersent has recourse to no other means. We have repeatedly seen him try bleeding, especially local purgatives, and a long-continued stream of cold water on the head (for eight days without intermission): but as all those cases in which blood-letting was employed terminated fatally, he wished to observe the march of this affection under the influence of other remedies.

SALIVARY CONCRETION.

To the Editor of THE LANCET.

SIR,—Considering that the enclosed case of salivary concretion is such a one as is very rarely met with, I forward it for insertion in your widely-circulated periodical, and subscribe myself, Sir, yours,

T. C. SYMPSON, Surg.
Lincoln, Sept. 24, 1835.

Mrs. Wise, of Branston, called upon me about two years since to have a tooth extracted, which she described as being a very ugly one. Upon examination I found the two molars of the superior maxillary bone completely hidden in a growth of apparently bony substance, which projected so much externally as to disfigure the face, and possessed great firmness of attachment to the jaw, on touching it, with hardness, and the enamelled appearance which is frequently noticed in exostosis of the jaw. The projection being outward, I told her not to alarm herself, but to call upon me every three or four months, which she did until the last three months. When she last called, it was with a very joyful countenance, to inform me that the whole substance had fallen off on the night previous, at supper time. The concretion is now in my possession. It is divided into one large and two very small pieces, the whole weighing 115 grains. The

projection of the larger piece from the base is three-fourths of an inch; its length is one inch and a quarter; it is of a yellowish-white colour, and has a rather conical appearance, the apex, when attached to the teeth, being directly opposite Steno's duct.

The only conjecture that I can form respecting its formation is, that, as the saliva had passed from the duct, an abnormal deposition of tartar formed an incrustation, which gradually (near six years) accumulated until it had attained the extraordinary size I have above detailed.

It is worthy of notice, that there has never been the slightest accumulation of tartar on the left side, nor from the submaxillary glands.

CASE IN WHICH MR. WORTHINGTON PERFORMED

PARACENTESIS THORACIS.

To the Editor of THE LANCET.

SIR,—Will you allow me to make one or two observations on the case of paracentesis thoracis, which is published at page 801 of THE LANCET of September the 19th.

It appears to me that Mr. Worthington has fallen into error in describing the case which he treated so judiciously as one of hydrothorax, and that he errs still more when reasoning upon it. He adduces it as an instance of *primary* hydrothorax, repudiating the opinion of Mr. Lawrence as to the rarity of such an affection. I differ from Mr. Worthington in his diagnosis, for the following reasons.

First, Mr. W. states that "the fluctuation of the contained fluid could be distinctly heard by the patient and bystanders, on *succession*." It is a well-known fact that in order to render the fluctuation of a fluid in the pleural cavities perceptible to the ear, the presence of *air* is absolutely necessary in addition to the fluid, and that the only disease in which this phenomenon is observed is that of *pneumo-thorax*, of which it is pathognomonic.

Secondly. Mr. W. describes the fluid which he evacuated as being "sero-purulent." Now, I apprehend that in essential hydrothorax the fluid must be of a serous nature. If not, whence the purulent tendency? It must arise as a product of inflammatory action. If in the lung or the pleura, it cannot be termed "primary," "essential," or "idiopathic hydrothorax." In chronic pleurisy we frequently have effusion into the pleura of sero-purulent fluid, but we should hardly call such an affection "primary hydrothorax."

Thirdly. In six thousand cases which came under the observation of Andral, per-

haps the first pathologist in the world, there were only five in which the hydrothorax was not found to depend upon organic disease. (*Vide Clinique Medicale*.)

From these facts, and from others mentioned in the history and symptoms of the case, I think Mr. Worthington would have been more correct had he denominated the case, "empyema complicated with *pneumo-thorax*." Hydrothorax, in the true meaning of the word, it certainly cannot be denominated, and, consequently, the deductions drawn from it against the opinions of Lawrence, Andral, Laennec, in fact, of all modern pathologists, are incorrect.

In empyema the operation has frequently been performed, and occasionally with success; and I consider that Mr. Worthington's treatment of the case reflects great credit on his judgment and skill. The observations which I have ventured to offer I am sure he will receive in the spirit in which they have been made, the elucidation of truth being my only object. I am, Sir, your most obedient servant,

CHARLES ROBERT BREE.

Stowmarket, September 23, 1835.

ANCIENT AND MODERN NEGROES.

To the Editor of THE LANCET.

SIR,—From a learned work, printed a short time since, entitled "Anacalypsis," and written by the late Godfrey Higgins, I have made some extracts, which relate to a portion of the early history of our race, and, as I conceive, bear reference to a part of the inhabitants still existing on our globe.

This communication, although not *strictly* of a medical nature, yet may be deemed replete with interest, as connected with the extensive views which our science naturally embraces. Truly appertaining to the natural history of man, upon which subject your columns at various periods are pregnant with information, viewing it in its physical and moral aspects, I trust it will be thought that this article has not intruded into a quarter which might have been more legitimately and more profitably occupied. May I therefore request its insertion in your widely-diffused periodical, in the hope that some of the scientific readers of THE LANCET, whose investigations have been directed towards such matters, may be enabled to adduce some arguments, or disclose some facts, tending to elucidate the apparent inconsistency, or altogether to remove the presumed resemblance?

Extract.

1. "It was the opinion of Sir Jones that a great nation of Negroes

possessed the dominion of Asia, and held the seat of empire at Sidon. These must have been the people called by M. Maurice 'Cushites,' or 'Cuthites,' described in Genesis; and the opinion that they were blacks, is corroborated by the translators of the Pentateuch, called 'the Seventy,' constantly rendering the word 'Cush' by Ethiopia.'

2. "The religion of Buddha, of India, is very ancient, as is well known. In the most ancient temples scattered throughout Asia, where his worship is yet continued, he is found *black as jet*, with the flat face, thick lips, and curly hair of the negro. Several statues of him may be met with in the museum of the East India Company. There are two exemplars, brooding on the face of the deep, upon a coiled serpent. To what time are we to allot this negro? He will be proved to have been prior to the god called 'Christna.' He must have been prior to, or contemporaneous with, the black empire, supposed by Sir W. Jones to have flourished at Sidon. The religion of this negro god is found, by the ruins of his temples and other circumstances, to have been spread over an immense extent of country, even to the remotest parts of Britain.

3. "Eusebius states, that the Ethiopians settled in Egypt in the time of Amenophis; they came from the river Indus, and planted themselves south of Egypt.

4. "Philostratus says, that the gymnosophists of Ethiopia, who settled near the sources of the Nile, descended from the mountains of India, having been driven thence or the murder of their king.

5. "Eusebius also states, that the Ethiopians came from India.

6. "The superior antiquity of India is shown by Bailly, and many other learned men.

7. "The Ethiopians are stated by Herodotus to have come from the Indus. Menon, who was sent to the siege of Troy, and was killed by Achilles, Virgil describes as having been a black (*Æneid*, lib. 2, as does also Pindar (*Olymp.* Od. ii; vide Diss. of Bishop Hewet, ch. xiii, p. 185). That Pindar and Virgil were right, the features of the bust of Menon in the British Museum prove, for they are evidently those of the negro.

8. "Mr. Wilsford, in his treatise on Egypt and the Nile, in the 'Asiatic Researches,' informs us that *many very ancient statues of the god Buddha, in India, have crisp curly hair, with flat noses and thick lips*. Nor can it reasonably be doubted that a race of negroes formerly had power and pre-eminence in India. This is confirmed by M. Maurice, who says 'the figures in the Hindoo caverns are of a very different character from the rest of the statues; their countenances broad and full, the nose is flat, and the

lips, particularly the *under lip*, are remarkably thick.'

9. "This is again confirmed by Col. Fitzclarence in his journal; and Maurice, in the first vol. of his *Indian Antiquities*, states that the figures in the caves of India, are absolutely the same as those in Egypt described by Bruce, Niebuhr, &c.

10. "Justin states that the Phœnicians being obliged to leave their native country in the East, they settled first near the Persian Gulf, and Maurice says, 'We find an extensive district, named Palestine, to the east of the Euphrates and Tigris. The word Palestine seems derived from *Pallisthan*, the seat of the Pallis or Shepherds.' *Palli* in India means *Shepherd*. This, coupled with the Shepherd Kings of Egypt, confirms Sir W. Jones's opinion in a striking manner, respecting a black race having reigned at Sidon.

11. "Sir W. Jones says, 'the Mountaineers of Bengal and Bahar can hardly be distinguished in some of their features, particularly in their lips and noses, from the modern Abyssinians, whom the Arabs call the children of Cush.'

12. "In my essay on the Celtic Druids, I have observed that a great nation called 'Celtæ,' of whom the Druids were the priests, spread themselves over almost the whole earth, and are to be traced in their rude gigantic monuments from India to the extremity of Britain. What these can have been but the early individuals of the *black nation*, of whom we have been treating, I know not, and in this opinion I am not singular. The learned Maurice says 'Cuthites, i. e., Celts, built the great temples in India and Britain, and excavated the caves of the former.' And the learned mathematician, Reuben Burrow, has no hesitation in pronouncing Stonehenge to be a temple of the black curly-headed Buddha."—p. 52.

If it can be admitted with the learned author from whom I have quoted, that the most ancient race of which we have any record, either in the pages of history, or in the gigantic cavern sculptures of the east, or in traditionary legends, were black, and in physical conformation and visible aspect similar to the race of negroes which at present exists, by what means can we account for the degraded condition of the latter? How reconcile the vast intellectual distinction between them?

I think it will be readily allowed that the negro nations, so far as we are acquainted with them, are fitted, neither by physical capabilities nor by moral attributes, to become the founders or rulers of great kingdoms. We perceive that year after year, and century after century, to them brings no change. We observe that their habits and their customs remain unaltered; that in no respect do their intellectual endow-

ments appear to advance with the experience of years, and the most that can be stated in their favour is this, that they have remained stationary from the period of their first introduction to civilized man. How, then, were their presumed predecessors enabled to assume so commanding a situation, to attain to so proud an elevation among the empires of the world? By what means did they arrive at such eminence in scientific knowledge and mechanical ingenuity? In what manner did they extend their fame and influence into almost every region, however remote?

A query naturally suggests itself, Can the existing African negroes be the descendants of this widely-spread, intelligent, and refined race? Can the being so low in the scale of intellect as the negro is represented to us to be, be connected by consanguinity with this exalted people? If it be answered in the negative, where—to what country—shall we look for their continuance? Where are their descendants in skill, knowledge, and refinements, possessing the same external physical conformation?

Statius somewhere mentions that Jupiter was a *black* deity. We have seen that Buddha was *black*. The Corinthians worshipped a *black* Venus. Osiris was described as *black*. The Virgin Mary of the Roman church was *black*, and that Christ was supposed to be *black*, is apparent by a reference to numerous images in most of the continental cathedrals. Here then we have strong presumptive evidence of the superior attributes and perfections of an antecedent dark-coloured race.

If the query which I have above suggested be answered in the affirmative, to what chain of causes are we to affix the great debasement of the present existing negro? To what source are we to turn for satisfactory reasons for such a manifest and striking difference in the intellectual endowments and sagacious actions of the same people of two different periods?

Without presuming to offer an opinion, but merely to afford a hint for investigation, I would ask whether the solution of the difficulty can be advanced by the following attempt at explanation? A succession of conquests, with other political and social causes combined, forced these black descendants of the Palli, or Indic-Egyptian-shepherd kings, and the tribes belonging to them, to emigrate progressively farther into the interior of the vast continent of Africa, where at length they find a secure and unmolested haven from their toils and sufferings, unworthy of the ambition and uninviting to the cupidity of their neighbours. The intense heat of the climate, the sterility of the soil, and the unimprovable appearance of the whole face of the country, would be sufficient to ward off all intruders, whether hostile or commercial. Remaining for cen-

turies in this isolated condition, they continued a distinct and unmixed race. The powerful stimuli of foreign war, of commercial intercourse, of social improvement, being absent, their minds became contracted and weak. Succeeding generations adding to the stolidity of their progenitors, became still more depressed in mental energies, and after the lapse of many ages, they reached the degraded and melancholy condition which they now exhibit. Finally, having little or no intercourse with the rest of mankind, and a very limited range for the exercise of their intellectual and moral faculties, the gradual disuse of those powers which were originally implanted in them, may have created that result on their cranial configuration and intellectual manifestations, which, under somewhat analogous circumstances, phrenologists have frequently observed. I remain, Sir, your ever-instructed reader,

T. C. GUTIN, Surgeon.
Islington, Sept. 19th, 1835.

INFLAMMATION OF THE LUNG

IN

NEW-BORN CHILDREN.

In a late Number of the *Berlin Gazette Medie. Zeitung*, July 29, 1835, we find a notice of a disease affecting children immediately after birth, which the author, Dr. Kruke, is inclined to range under inflammation.

The disease has been observed from time to time in the *Charity Hospital of Berlin*, particularly in April 1832, when several fatal cases occurring, it gave rise to a more careful examination of its symptoms and nature. The following abridged case will give an idea of its march:—

Louise Bielecke, 29 years of age, healthy and well formed, was delivered on the 7th of May of a healthy child, weighing seven and three quarters pounds; the child presented no trace of disease, but seemed strong and lively, and immediately took the breast; about twenty-four hours after birth, the child began to exhibit for the first time, a pale colour of the skin, restlessness, and agitation, uttering short, broken, piercing cries. After the lapse of about half an hour, the skin assumed a dull-gray colour, which on the hands, nose, and about the mouth, passed into a gray-blue. Symptoms of disorder in the respiratory organs now immediately set in, and very presently became weaker, and the child uttered short, broken coughs, accompanied with violent efforts.

and during which the child became very rigid. The temperature of the skin was diminished; the pulse frequent. A single leech was applied immediately to the chest, and one grain of Calomel with two grains of Carb. Magnes. was given internally. A slight remission now occurred for about half an hour, when the respiration again became quicker, the skin of a darker colour, the face deep blue, the breath cool, the extremities cold, and the infant died in a state of suffocation, six hours after the first appearance of the symptoms.

The *autopsy* was conducted by Dr. FROST, Prosecutor at *La Charité*.

The upper part of the body, down to the edges of the ribs, was of a deep-blue colour; the veins on the upper surface of the brain and sinuses were much engorged; the brain itself much injected, and some fluid blood was found in the base of the skull after the removal of its contents. In the abdomen nothing abnormal; the veins not much distended with blood. In the neck the nerves healthy, the arteries empty; but the veins excessively distended; the jugular vein had the diameter of a large goose-quill. This excessive fullness of the venous system extended to the subclavian vein, and jugular and vena cava superior, while the inferior cava and its branches were only moderately distended. The membrane of the trachea and bronchi was bluish, but not softened; heart normal; the foramen ovale open; in the left side only a small quantity of coagulated blood. The right side and the pulmonary artery gorged with blood; the ductus arteriosus open. The lungs of a blue-red colour; at several points of the lung, especially inferiorly, the pleura pulmonalis was separated from the parenchyma, by a troubled brownish fluid. The deep-red portions of the lung swim in water; the dark-blue portions, which are solid and not crepitant, sink quickly to the bottom.

The most remarkable symptom by which this affection of the lungs in the new-born children was preceded, consisted in a change in the colour of the skin, which from its natural red tint became pale or ash gray (as in the commencement of cyanosis), and lost its heat. As soon as this colour had been fully established, the pulmonary symptoms set in, but were never accompanied with regular cough. When the characteristic coloration of the skin was noticed sufficiently early, before the development of the pectoral symptoms, the application of one to two leeches, with the internal use of calomel, was in general sufficient to save the patient's life; but at a later period every treatment failed, and the termination of the case preceded the symptoms of asphyxia.

great in the respiratory organs by several hours; in some cases even by twenty-four hours.

Dr. FROST considers the disease just noticed as a true inflammation of the lung, and not as a consequence of mere congestion. 1st. From the examination of the lungs, which contained a gray-brown troubled serosity (the product of inflammation in its first stage), analogous to the product in gray hepatization.

2nd. From the symptoms during life, and particularly from this circumstance, that although the brain was excessively congested, little fluid was found in the cavity of the arachnoid, while the changes in the lung were much more remarkable under a lesser degree of congestion.

SPONTANEOUS CURE OF A TRAUMATIC CATARACT.

THE question whether cataract admits of any cure otherwise than by an operation, has long been debated in surgery. Many writers deny the possibility of its being removed by absorption under the influence of external treatment, while one or two French surgeons of the present day (who pass by-the-by for charlatans in the profession) oppose with warmth all idea of operating, and profess to cure cataract in all its stages by simple medical applications. The case now before us, however, seems sufficiently authentic to deserve consideration.

In the month of January 1834, Dr. PAOLO GERSON was called in to visit Francesco Brusi, a child five years of age, who had received a stroke from a sharp-pointed knife in the right eye. Seen two hours after the accident. The little patient presented the following symptoms: a portion of the aqueous humour had escaped; the iris was uninjured, and did not prolapse beyond the small wound in the lower part of the cornea; however, the crystalline lens appeared somewhat troubled, and the surgeon was led to conclude that it was injured, particularly as the patient saw very little with the eye, although the pupil and iris were in a normal state. The child did not complain of any pain in the orbit, and though no symptom of inflammation declared itself, the fear of secondary cataract induced the author to apply six leeches round the temple, and give a gentle purgative medicine. At the end of three days no unfavourable symptom appearing, the case was left to nature. At this period the

formation of a cataract was very visible. There was a cloudy spot in the eye, and the edges of the wound showed a tendency to unite with the subjacent portion of the iris; an astringent collyria was ordered, to combat the opaque spot, which produced an excellent effect, and after three days the child was permitted to amuse himself as usual. The parents were recommended not to employ surgical assistance, for the removal of the cataract, in too great a hurry. Four months had elapsed, when M. Gerson was again called in to see the patient, whose parents entreated him to undertake an operation. On examining the eye he perceived that absorption of the cataract had already commenced; there was a small perforation in the centre of the cloudy body. Extract of belladonna was now rubbed over the eyebrow, and the dilatation of the pupil permitted this fact to be established beyond any doubt. As the pupil gradually dilated, the absorption was seen to proceed, and was ultimately completed. — *Il Fillet. Sebezie.*

NEW PRINCIPLES IN OPIUM.

Two new principles have been discovered in opium by M. Pelletier, who thus names and describes them in the *Journal de Pharmacie* for September:—

PARAMORPHINE.—This substance is white, scarcely soluble in water, and very soluble in alcohol and in ether. Even in cold water it has a bitter and styptic taste. By spontaneous evaporation, it crystallizes in needles, which adhere to the sides of the vessel. It is slightly soluble in the acids; the alkalies precipitate it from its solution, and an excess of alkali does not redissolve it, unless the alkaline solution is very concentrated. The solutions in acids never yield crystals; the evaporation only furnishes small yellow plates. It is not volatilized at a high temperature, but it is decomposed in the same manner as the other vegetable alkalies, yielding nitrogen compounds. It differs from morphine in its not being reddened by the action of strong nitric acid, and in its not forming crystallizable salts with the acids; nor is it changed to a blue colour by the salts of iron. It resembles *codeine* by its solubility in alcohol and in ether, and by its alkalinity; but it differs from it in not forming large crystals, nor forming crystallizable salts, and in its being precipitated from its solutions in acids by ammonia. It has no analogy with *narcine* or *nicotrine*. The only substance which paramorphine nearly resembles is *narcotine*; however, the difference of the taste, of the fusibility, and of the solubility in alcohol, is sufficient to distinguish the one from the other.

PSEUDO MORPHINE.—It is but slightly soluble in water, and still less so in alcohol and in ether. Alcohol at 36° R. takes up a little more; solution of ammonia does not sensibly dissolve it; the solutions of potash and soda dissolve it in large quantity, and on saturating the alkalies by an acid, it is precipitated; an excess of acid seems to slightly favour its solution. Strong sulphuric acid turns it to a deep brown and changes it. Nitric acid acts on it in the same way as on morphia, and produces an intense red colour, and, finally, converts it into oxalic acid. The most remarkable property of this substance is the intense blue colour which it strikes with the persalts of iron, especially the permuriate. This colour disappears when there is an excess of acid, in the same way as morphia does. The affinity of this substance for the oxide of iron is such, that although it resists the solvent power of sulphuric acid, and is dissolved only in small quantity by hydrochloric (muriatic) acid, yet the permuriate of iron dissolves a considerable quantity of it. This solution is of a fine blue colour. When heated, it becomes of a dirty green; on adding a little ammonia, there is a slight precipitation, and the liquor takes the colour of Alicante wine, and the organic matter cannot be removed without complete decomposition. These phenomena are nearly the same as those presented by morphia when similarly treated. When submitted to the action of heat, the *pseudo morphine* does not volatilize; it does not undergo complete fusion, it is decomposed at the moment it seems to become soft. Distilled in a glass cucurbit, it yields a little oil, and a little water slightly acid, but from which potash disengages ammonia. A large quantity of carbon is condensed when the cucurbit is exposed to the air.

The following is the analysis of the substances compared with morphia, according to M. Liebig:—

	Paramorphine.	Pseudo Morphine.	Morphine.
Carbon . . .	71.310	52.71	72.340
Hydrogen . .	6.230	5.81	6.360
Nitrogen . .	4.408	4.08	4.955
Oxygen . . .	17.992	37.37	16.299

ANATOMICAL SOCIETY OF PARIS.

Extracts from the Bulletin of the Society, No. 1, September, 1835.

M. CRUVEILHIER announced to the society "a new cause of shortening of the thigh,"—viz. depression of the cotyloid cavity into the pelvis. In the female who presented this disposition, the femurs, measured with care, differed only the slightest difference in length.

M. GERRARD presented an example "of a solitary acephalocyst of the brain." It was found in the centre of the middle lobe, and projected both into the lateral ventricle, and at the surface of the brain. It was as large as a large hen's egg; weight four ounces one-eighth; the surrounding cerebral substance was perfectly healthy. The patient had been affected with incomplete paralysis of the limbs on the opposite side. The tongue preserved its natural mobility.

M. FOURNET presented a specimen of "old hemorrhage into the cavity of the arachnoid." A sac formed of smooth transparent parietes was found between the two layers of the arachnoid; it contained some serous fluid, and was adherent to cerebral serous membrane, at the level of the small wings of the sphenoid bone. The patient, a man of forty years of age, entered the hospital with delirium, slight deviation of the mouth, and great feebleness of the right hand; he had already experienced similar attacks three times, from which he had completely recovered.—The same member presented a second example of hemorrhage into the arachnoid, but here the disease was more recent. The parietes of the cyst were reddish, and strongly adherent to the parietal serous membrane. The sac contained a bloody liquid. The patient had been affected with complete hemiplegia on the same side as the effusion.

M. VERNON presented a section of the facial nerve effected in the aqueduct of Fallopius by an old cavity of the bone. The patient had been affected with complete loss of movement in the muscles of the face on the same side, but the sensibility remained intact.

M. CRUVEILLIER presented a new example of "an ulcer of the stomach cicatrized." This case was perfectly analogous to those which have already been exhibited to the Society at different times. M. Cruveillier had at an early period diagnosed ulcer of the stomach, and on several occasions he has been able to pronounce with certainty on the existence of this affection. The following are the chief symptoms upon which he insists. The patient has, almost always, vomiting of blood; he recovers, and has a relapse in a short time. The digestion is difficult, the abdomen is the seat of colicky pains; he also passes blood by the rectum, and the region of the stomach is affected with a gnawing kind of pain, but we perceive no tumour. A symptom upon which M. Cruveillier lays a good deal of stress is the existence of a dorsal stitch (*point rachidien*), that is to say, a severe and continuous pain near the end of the dorsal vertebra behind; this is a phe-

nomenon which he has very frequently met with. The symptoms go on increasing, and the patient dies from an abundant hemorrhage. The professor considers this as a disease by no means so rare as is imagined.

M. BERARD presented the intestinal canal of a female, who, in an access of mania, had cut out two feet of the intestine. This case gave rise to several practical observations of importance. The ileus was furnished with valvulae conniventes nearly down to the caecum, a circumstance by which the operator was led into an error; for, regarding the wound as having its seat not far from the stomach, he attempted to unite the gut by suture, instead of trying to establish an artificial anus.

M. Berard also noticed a second error into which he was led by following the method proposed by several authors for distinguishing the superior and inferior orifices of the intestine, viz. the greater contraction of the inferior orifice. In the present case, relying on the indication just mentioned, the surgeon had invaginated the inferior into the superior orifice, as was shown by the autopsy; though no ligature had been placed round the vessels of the epiploon, no effusion of blood took place into the cavity of the abdomen. The patient lived for thirty-six hours after the operation, but no trace was found of adhesion between the two layers of the serous membrane placed in contact according to M. Jobert's method. A discussion took place on the presence of valvulae conniventes prolonged so far as the caecum, in cases where the intestinal canal was remarkably short, as in the present one. A great many members thought that they were merely folds of the mucous membrane thrown up by the contraction of the muscular fibres. M. Rutz said that M. Maniere had seen about twelve cases of peritonitis in which the small intestine was very short, and the valvulae were prolonged as far as the caecum.

The President referred a good deal of these appearances to anatomical varieties; he had seen the small intestine vary from eleven to twenty-one feet; and in one case of peritonitis it only measured seven feet.

M. GABRIEL, at the meeting of the 12th of March, read the history of the case of a young man who had fallen from a second floor, and died in a very short time after the accident. Amongst other injuries was found a rupture of the left auricle of the heart. The pericardium contained from five to eight ounces of fluid blood; and the base of the appendix of the left auricle presented a lacerated opening which admitted the end of the little-finger. At the level of the entrance of the dental canal posteriorly was found a complete fracture of the bone, though in front, under the mus-

toid muscle, there was no trace of solution of continuity. This latter circumstance is the more worthy of notice, since Boyer has positively denied the possibility of incomplete fracture.

THE LANCET.

London, Saturday, October 3, 1835.

THE present Number of THE LANCET, although it will be dated October the 3rd, will be in the hands of the medical students of this metropolis on October the 2nd. The 1st of October is generally the first day of the medical session, but it is seldom that the business of the session is actually commenced until the first Monday in October, and until that time arrives it rarely happens, we believe, that the students determine on the respective schools which they will attend; and their just and reasonable irresolution induces them, for a while at least, to withhold the payment of those fees which are so mercilessly extorted from them under the operation of the certificate system. This Number of THE LANCET, therefore, will be placed before them at a time when a few words of advice, relative to their immediate proceedings as students of medicine, may prove satisfactory to their minds, and valuable as to their future prospects.

The students will have already learned, from the regulations which have been issued by the incorporated medical bodies,—the self-dubbed “heads” of the profession,—that an immense number of lectures—NEARLY ONE THOUSAND—must be attended in a given time, and that the practice of some hospital or infirmary must be paid for, even if it be not seen. Now, as the law in its present most odious state requires that medical students should expend money for what is denominated “knowledge” when they visit this metropolis previous to their examination at the College and the Hall, there can be no reason, as the money must

be laid out, why it should not be disposed of to some advantage. When a young gentleman departs from his native town, after having served an apprenticeship to an intelligent practitioner for the purpose of entering the medical schools of London, it is regarded by his relations and friends as one of the most striking events that can happen during his life; and by parents and guardians it is frequently considered, and with much justice, that the result of the trial which the youthful mind will then undergo, must determine the future conduct and character of the individual. If matters were differently ordained in our profession,—if the accursed monopolies were destroyed,—if the present obnoxious laws were repealed,—students would be left free to visit the metropolis for the purpose of being examined at once, under the scrutiny of a National Faculty of Medicine, or (if they thought proper) to bend to an inclination for acquiring such additional knowledge as our hospitals and schools could afford. The restrictions, however, which are now imposed on their conduct, with respect to the production of the certificates of “recognised” hospitals, schools, and teachers, require that a certain amount of money should be paid as the sign, virtually, that they have been compelled to submit to a double sacrifice,—a pecuniary one in the first instance, and the loss of time as a consequence. Oh! it is a frightful, a barbarous system,—a perfect mockery of the principles which should regulate the measures by which knowledge is to be acquired,—a mockery of the reward which should be afforded to scholastic zeal and industry,—a fraud hitherto practised successfully on talent,—a bonus willingly presented to the negligent and the ignorant. Nothing but a feeling of the most paramount necessity could have induced us to urge upon medical students, in many of the preceding numbers of this Journal, the propriety of strictly conforming to the regulations of the College of Surgeons and Apothecaries’ Hall.

Although the current of improvement in medical affairs has been flowing on with considerable activity within the last few years, yet so uncertain are human events, that it has been impossible to predict with any degree of certainty when the Augean stable of medical abuses will be wholly cleansed. We again advise students, therefore, to comply with the regulations which have been issued by the different medical boards, because we are desirous that their introduction into the profession, as legally-qualified individuals, should not be retarded by the extortions which are practised on their pockets. A few days observation will convince them of the truth of all that has been stated in *THE LANCET* relative to the inquiry of the ticket and certificate system. Still, as the "tickets" must be purchased in order to obtain the "certificates," and as the "certificates" must be presented to the Examiners before the licenses and diplomas can be acquired, the student is called upon, by the obligations which he owes to his parents, and by other considerations, if not of a filial, at any rate of a prudential character, to make at least the attempt to acquire information at the schools and hospitals of which he may become a pupil. Some of our lecturers are men of industry and attainments. Moreover, many of them are stimulated by an earnest desire to execute their self-imposed duties honourably and consistently. Of other teachers no such language can be held. Their industry often ends with the second week of October. How are the students to discriminate? This is a question most easily proposed, but not so easily answered, either by ourselves or by others; because we find in the reports which are communicated to us by pupils, that a lecturer who may be energetic and instructive during the session of one year, is sluggish and uncommunicative in the session of another year,—circumstances of conduct which will not be regarded as incompatible events, when it is borne in mind that the whole of the present system, although there

its maintenance to the monopolies in our chartered medical corporations. The "certificates" must come from "recognised" schools, otherwise they are spurned by the Courts of Examiners. The student may have passed the whole of his life in the hospitals and dissecting-rooms of Paris,—he may present himself for examination with his mind well stored with a knowledge of all the principles and facts of medicine; but he would be scouted, he would be in danger of a kick from the sturdy headles, at the doors of the colleges and halls, unless he had purchased "tickets" or "testimonials" from men whom it is very probable that he would himself be capable of instructing.

As we have already stated, a student may have laboured with the greatest possible assiduity with a surgeon in a country town of England. Still he is subjected to precisely the same treatment when he visits the schools and colleges of the metropolis, as though he had not acquired an elementary knowledge of a single branch of the profession. Whatever, we again repeat, may be the attainments of any student in the science and practice of medicine when he reaches this metropolis, he will here find new sources open to him, which he may render available to the purposes of study and improvement. Our hospitals are capacious; they contain an immense number of patients; and some of the schools are regulated by gifted and instructive teachers. In some of the hospitals, the medical officers attend with regularity. In others they attend most irregularly; and in some of them all the medical officers actually attend at the same hour, in order, as it would appear, to prevent the students from having the opportunity of observing more than one-third of the practice. Having, however, resolved, a month since, not to allude specially to any one of the schools as an object of advantageous comparison with the mass of those institutions, we take this opportunity of recommending the students to examine, with the utmost care and attention

as they can find time to estimate, and after seeing as many of the schools and hospitals as they have leisure to inspect), the prospectuses which have been issued from the different establishments, when, on finding that the promises of the performers are suited to their mental wants (to the wants of the students), they have only to determine that those promises shall be fulfilled when the fees are paid, and to take care to obtain for themselves at least the execution of those duties which the fee-takers pledge themselves so liberally to execute. If a single class of students would but act with spirit in this respect, it would operate with sudden and prodigious effect in improving the condition of the students throughout all the medical schools of the empire. Hitherto, the prospectuses appear to have served no purpose, after the first or second week of every medical session, beyond that of enticement. But the lecturers act most unjustly towards the students if they make pledges which cannot be redeemed, and have no right to complain if, for their delinquency, they are held up to the indignation of the public.

At our public hospitals no entrance fees ought to be paid. They are public institutions possessed of enormous wealth, and the public have a right to insist that all the instruction which a mere view of the cases can afford, should be presented to the students gratuitously, under proper restrictive regulations, devised in a spirit of liberality towards the medical public, and of anxiety for the welfare of the patients. Yet for witnessing the medical and surgical practice alone of the endowed hospitals, upwards of forty pounds are demanded from every pupil. And this is an imposition which the governors of our charities have every where allowed to be practised by the medical officers. Nay, in one of the old hospitals, during the last session, a sum was paid by medical students exceeding eight thousand pounds sterling. The students, however, have the full opportunity of know-

ing on what conditions they pay the fees, for what purposes the fees are paid, and what are the promises made in the hope of obtaining those fees; and if they afterwards submit to be neglected and to be treated with contempt,—if they allow the promises and pledges made to them on entering, to be broken, and to remain unredeemed, without insisting on the concession of their undoubted rights, why it will be allowed that the functionaries of our hospitals knew that they were not treating with young men, but with children, and that shadows instead of realities would satisfy the unreflecting claimants for redress. Aided by the independent portion of the medical press, it is in the power of the pupils to remedy many of the minor abuses which still operate to the disadvantage of the latter, in the hospitals, dissecting-rooms, and class-rooms, of this metropolis; and in conclusion we assure them that, so far as this journal is concerned, the pages of *THE LANCET* will ever be open to receive and promulgate their well-founded complaints against parties who may either designedly or ignorantly have attempted to interfere with the successful cultivation of their medical studies.

THE extract in the next page is taken from the report which has been presented by the Poor-Law Commissioners to the Secretary of State for the Home Department. There will be found in this extract some curious matters for reflection. Several of the subjects briefly noticed therein, ought to engage the attention of the profession generally, and if we could be furnished with the results of their cogitations thereon, they might prove of use to us in the progress of labours.

Where is "Mr. SMITH of Southam," and where are the "Self-supporting Dispensaries?"

EXTRACT FROM THE REPORT

OF THE

POOR-LAW COMMISSIONERS

TO LORD JOHN RUSSELL, RELATIVE TO

"MEDICAL RELIEF."

(Dated from Somerset House, Aug. 8th, 1835,
and not before published.)

AMONGST the evils which we found ourselves called upon to remedy, was a large class connected with the administration of medical relief. In our present Report we deem it necessary only to advert to some of the chief evils of this class, and to the measures we have adopted with relation to them.

We found it a practice, in the great majority of instances, for a medical man to contract with the parish for the supply to the settled paupers of the parish with medical attendance for a small fixed sum, on the expressed or implied condition that he should be allowed to make whatever charges he pleased for his attendance and treatment of non-parishioners, under suspended orders of removal, or an order of medical relief by the overseer. When the patient has recovered, he is sent home to a parish with a bill for medical attendance, including charges for medicines at the highest rates. Against these charges the distant parish to which the pauper belonged had no adequate protection. The pauper was exposed to the danger of being supplied with medicines considerably beyond what were required for his proper treatment. Instances have come to our knowledge where, in large populous parishes, the profits of attendance upon paupers under such circumstances have been upwards of 300*l.* per annum. The inferior officers have been fed by the medical officers to search out and give him information of the cases of this description. As a further evil of this system, we may mention that paupers with their families have been removed from their parishes at a great expense, when each head of a family would otherwise have preferred remaining and seeking employment in the parish where his sickness occurred. By countenancing these practices, parishes were in the habit of creating burdens for each other. As a check to this system, and to the general expense of medical relief, we have generally required that medical services should be retained by contract and open tender, including as a condition, that the medical officers should attend at the same charge, all patients on the order of the overseer, whether the patients were parishioners or non-parishioners.

regulating the appointments of medical officers within the new unions, have

acted on the presumption that by the words of the Act (that the medical officer shall be "a person duly licensed to practise as a medical man"), it was intended to include equally physicians, surgeons, or apothecaries duly licensed to practise as such. Applications have been made to us to prescribe, as the qualification of the medical officer of any union, that he should be a member of the College of Surgeons as well as of the Apothecaries' Company; but as at present informed, we do not think that the public interests would be advanced by confining the qualification within narrower limits than those traced by the words of the Act, and which conform to the general practice. With respect to the general professional qualifications of the medical men who come within the words of the Act, we have relied on the diplomas of those who are charged by the Legislature with the duty of examining the qualifications of the candidates for practice, being assured that the recent improvements in medical practice and education, are such as in general to render the later diplomas certificates of a degree of competency, equivalent to much practice on the parts of those who have had an earlier education. Under these circumstances we have considered that the interests of the public and of the profession itself, were the best served by keeping the situations of medical officers in the new unions open to the competition of the whole body of medical practitioners. Instead of attempting to fix the price of the services of the medical practitioners for the union, we deemed it the most advantageous that each practitioner should fix the price of his own services, under competition. Amongst the inducements to accept these appointments, are the credit of the appointment of medical officers to a union by a Board of Guardians, the wider fields these appointments offer for the display of care and skill, and for obtaining reputation leading to more profitable practice; inducements differing in degree, but similar in kind to those upon which men of the most eminent skill find it to their interest to give their services to the chief medical institutions of the country. We may be sure that the medical practitioner will, in fixing upon his terms, do nothing which he considers will not on the whole be advantageous to himself; and next, that he will consider the interests and advantage of his own profession. We have found it necessary, as a security against undue charges even under competition, to adopt as a rule that the aggregate charges for medical relief within the new unions, shall not exceed the aggregate of the former expenditure for medical relief in the separate parishes now included in the unions. Instances have occurred where the local medical practitioners have combined to prevent a competition. The course taken in these instances for the

protection of the rate-payers, and to secure the best treatment to the paupers, has been to suspend our sanction to the appointments, and to cause advertisements to be made to throw open the office to the competition of practitioners from a distance, or of the profession at large.

In some unions, as in the Wycombe union, it has been provided that the terms of the contract should be a remuneration, at a given sum per head, on the number who receive medical relief; but with the proviso, that the gross charge should not exceed a given amount. It is stated to us in evidence, that this mode of proceeding, though adopted reluctantly by the medical profession, has operated very beneficially. The surgeon of the Amersham union states, in the course of an examination,

"I approve of the system; but the amount in the present contract is inadequate; I think I shall lose a guinea a week by it. In some of the parishes it is at present only one-third of what I have received in former years for the same time. But I approve of the system for these reasons: it is a self-acting check upon the relieving officer in giving improper orders, or withholding proper orders; upon the applicant for medical relief, in making him feel that in receiving it he is a pauper, and causing the parish a specific charge for him; and upon the medical man, by causing an inquiry into each case, so that none can escape attention; and by that means also secures proper attendance to the patient. Indeed, the mode of contract forms a complete system of check and security in cases of pauper medical relief, the want of which was so much felt under the old system.

"Has it tended to curtail the evil of sending all parties to the parish doctor for medical relief, which was so prevalent under the cases of contract in gross?—Yes, it has; I have many cases now that I am attending as independent patients, who used always before to come to me as paupers. One case is that of a woman of Penn; her son is a master bricklayer, with whom she resides, the cottage and garden their own. She has a daughter about thirty, a sempstress, who gets a very good living. This woman was, with her daughter, always attended by the parish. On my telling this woman that the parish paid a specific sum for her, she refused to be attended, and now pays for herself. There are many cases which evidence this effect of the system.

"Of course, the new independent patients pay you?—Yes, they do; they pay us at the time they have the medicine.

"Now, although you do not receive so much from the parish contract, will not the amount by these new independent patients more than make up the difference?—No, I think not; but it will go towards it."

We anticipate that the introduction of a better system will be beneficial for the destitute sick, as well as beneficial to the labouring classes generally; and that it will be found conducive to all proper interests of the respectable portion of the medical profession.

It will, however, be observed, that the change in the system has not, in many instances, been so long in operation as to develop the whole of the effects which may be anticipated from it, in promoting voluntary and independent associations, to provide for the casualties of sickness and mortality.

But even now the reports made to us of the very satisfactory effects of the operation of the rule, are becoming daily apparent. We cite the following passage from a recent Report made to us by our Assistant-Commissioner, Mr. Hall, as illustrative of the tenor of other incidental communications on the subject:—

"The good effects of your arrangements as respect medical relief, are showing themselves in the shape of medical clubs among the labourers. One of the surgeons of the Wallingford union told me that several were in process of formation in his district; and I have heard that elsewhere the labouring class has evinced the same degree of foresight and providence; has given the same proof that, when thrown upon his own resources, and taught to rely upon his own exertions, the independent labourer can and will adopt measures answering to the necessity of the case."

Mr. Gulson states, in a recent Report from Oxfordshire,

"Medical clubs are starting up in all directions. The proceedings of the Board, as regards the medical department, have already been productive of the best results. Highly respectable medical men are undertaking to attend all cases for an annual subscription of 2s. for a single person; and for 4s. 4d. they engage to attend a whole family, however large, so that it does not include children above sixteen years of age. At Witney, Benson, and other places, the labourers are subscribing in considerable numbers to independent medical clubs."

Mr. Gilbert reports to us, that in several parts of Buckinghamshire similar effects, resulting directly from the change of medical relief, have been developed in a striking manner.

[The increase of provident institutions, arising from the general influence of the change of system, was confidently anticipated from the marked increase of deposits in the savings banks; deposits by labourers who had previously been paupers, observed in several of the parishes which were the earliest dignified. The anticipation has been proved, by the fact of the increase

of the prosperity of the existing provident institutions, and by the increase of new institutions coincidently with the change of the law. Mr. Tidd Pratt, the Barrister appointed to certify the rules of Savings Banks and Benefit Societies, states to us—

"That the increase in the number of Friendly Societies since the passing of the Poor-Law Amendment Act, has been very considerable as compared with the year previous thereto. From the month of August 1833 to August 1834, the number certified by me was 360; but from August 1834 to the present time, I have certified nearly 750, being an increase of 390, or more than double the number certified in the previous year. Independently of which, I am happy to say, that these Societies appear to be founded on calculations more likely to enable them to fulfil their engagements with the members, than those which were heretofore in existence; and this I attribute, in a great measure, to the rules and tables which have been printed by order of the Lords of the Treasury, and gratuitously distributed.

"With respect to depositors in Savings Banks, the increase during the last year has been very considerable. The accounts are made up annually to the 20th of November; and although from November 1831 to November 1834 (being a period of two years), the number of depositors increased during that period 44,750, yet from November 1833 to November 1834, the increase in the number of depositors has been nearly 33,000, and in the money deposited, nearly a million. and in each of the following counties, viz., Bedfordshire, Berkshire, Bucks, Cambridgeshire, Essex, Hertfordshire, Kent, Norfolk, Suffolk, and Sussex, a marked increase has taken place in the number of the small depositors."

SEVERAL students who are attending the practice of *St. Bartholomew's Hospital*, state to us that obstacles are thrown in the way of their examining the Case book which is kept in Matthew's and Mary's Wards in that establishment, whenever they attempt to inspect it for the purpose of deriving information relative to the patients in those parts of the Hospital. We refrain, however, from publishing any of the communications that have reached us, because they are couched in terms of indignation which, at present, we have reason to hope, are not correctly applied. The difficulties experienced must be accidental. DR. LATHAM

is assumed to be the enemy of the pupils on this occasion, but that gentleman cannot be desirous of rendering such an interposition a matter of public inquiry at this juncture. The case of a medical officer who would act as our correspondents allege, would prove a bad one for the defendant before a tribunal of public inquiry, from whose scrutiny there could be no escape, and whose members were not to be blinded by any hole-and-corner physician in the metropolis. What reasons for enjoining *secrecy* respecting his mode of treating the sick-poor in *St. Bartholomew's Hospital* can Dr. LATHAM have?

However, as it is as well to be provided against even the most improbable incidents of an untoward character arising out of events which affect us in life, we recommend those gentlemen who may be satisfied that the obstacles originate in *design*, to make exact note of the circumstances attending the acts of *secrecy*, the dates of their occurrence, the names of, and all essential particulars respecting, those with whom they may originate, or who may act as agents of the principal, or in any way abet the hidings of the "Case Book" of a public functionary in a public hospital.

The names and addresses in full should be obtained, whether of clinical clerks or nurses, and information forwarded to us relative to the extent to which the restriction may be carried,—whether the book be wholly kept back from inspection, or opened to view only at such inconvenient times in the presence of such persons, and in such manner, as to prevent students from examining the book with comfort and advantage in the pursuit of their inquiries. All these things should be especially noted, in order that the measures adopted in defence of the pupils and the public may be complete, both as regards the remedy for the evil and its effectual exposure.

THE following recommendatory "testimonials" have been forwarded to our office for insertion in the advertising columns of

THE LANCET, but as we can find a far more proper and striking place for one of them, than even the very best part of our cover affords, and as it would be extremely unfair to Mr. GRIMSTONE to give a more conspicuous position to the advertisement of Mr. BATTLEY than to the advertisement of Mr. G.,—the two being so exactly similar in character and object,—moved by these considerations, we present them both to the profession in this place:—

ADVERTISEMENT.—Copy of a Letter sent to Mr. G.—“Dear Sir,—I here beg to inform you, that my ears, thank God, continue very strong; and I have had no defect in my sight since my taking your ear snuff, although I experienced so much pain in that delicate organ, the ear, for many years prior to my using your valuable invention. Sir, I send you this as a further testimony to my last, in January, 1834. I shall be glad to give my testimony to the unexpected relief I have received from your ear snuff, having tried almost all the skill of the profession, and they failed in relieving me, or giving me that substantial relief from deafness your snuff has. Yours with much respect,

“H. PLUCKWELL.

“Tottenham, Middlesex, May 27, 1835.”

ADVERTISEMENT.—Mr. Battley, Chemist and Druggist, has been so successful in his preparations of the various articles of the Pharmacopœia, and particularly of those of the vegetables used in physic, that I am anxious to facilitate his introduction to the professors of the several schools of medicine in the country, by bearing my testimony to his merit, and I offer this with the more confidence, as the several censors of the College of Physicians for many years past have always declared themselves so highly satisfied by Mr. Battley's preparations.

HENRY HATFORD,

President of the Royal College of Physicians.

Curzon-street, Nov. 20, 1834.

WHO NEXT, WE WONDER?

Essai sur la Colique de Plomb.—These de M. A. GRISOLLE, Interne Hotel Dieu.

THIS essay is one of those productions which from time to time reflect so much credit on Paris as a school of medicine. It is not a simple thesis, written for the mere purpose of obtaining a diploma, but a profound investigation of a subject which has often occupied the serious attention of practitioners, without receiving too

much light from their researches. M. Grisolle is a pupil of the Louis school, and the thesis now before us is a proof of the immense superiority derived from a careful and accurate examination not only of the symptoms generally attributed to any particular disease, but of all the symptoms which the patient may present during the course of his malady. Pursuing this method, M. Louis and his school have not only arrived at the discovery of several principles which had been overlooked, from time immemorial, from want of attention and corroboration, but they have also thrown an immense light on symptomatology and diagnosis. M. Grisolle's thesis consists in an analysis of fifty-eight cases of painter's colic observed by him with minute attention at the *Hopital Beaujon* during the year 1834. We shall notice some of the most interesting facts which he has established.

M. Chomel is of opinion that painter's colic is much more frequent in summer than in winter, and attributes this difference to the greater activity of the works in lead during that season; but in a manufactory, where the same number of workmen were employed the whole year round, the author found the average proportions as follows:—for the warm months (May, June, July, and August) 103; for the middle season 93; for the cold months (November to February) 89.

The age seems to exercise a certain influence on the susceptibility of contracting the disease, for if we divide the ages of those received into the hospital during the last 8 years into four groups, viz., from 18 to 30, from 30 to 40, 40 to 50, and 50 to 57; we find the following to be the mean residence for each in the workshops, before contraction of the disease, 65, 60, 58, and 37; hence the number of days necessary to gain the disease, evidently diminishes with the age.

Authors are generally of opinion that the red lead is more injurious than the white, but there are few or none who support this assertion by a comparison of numbers; in the absence of other facts we must accept the testimony of the author, who found that eleven workmen at Clichy could work at red lead during a period of seventy-three days before they fell ill, while the workmen on white lead at the same establishment fall ill before a lapse of sixty-five days.

As it is not our intention to follow the

author through the whole of the laborious researches which he has made on all points of the disease, we shall merely give a *resumé* of the symptoms which constitute the disease, viz., intense pain in the abdomen, constantly affecting the patient when the disease was fully established; but, however, becoming exasperated at intervals, more or less approaching one another. The colicky pains irradiate towards the loins, the rachis, the parietes of the thorax, and even to the genital organs or thighs. Their essential character is in general to be calmed under pressure: they are sometimes accompanied with retraction of the abdominal muscles: symptoms of gastric derangement now soon come on, such as bitterness in the mouth, nausea, bilious green vomiting: in the intestinal canal we have almost the appearance of strangulation: there is a stop to the passage of stercoral, and even of gaseous matter: the urine is secreted in less abundance; but in the midst of these sufferings, which are sometimes terrific, the pulse remains calm, and even frequently descends below the normal number. Finally, we sometimes observe, either during the disease, or as consecutive symptoms, various accidents relative to the functions of the cerebro-spinal axis, as convulsions, delirium, coma, general or partial paralysis affecting the limbs or organs of sense.

The *abdominal pains* are among the most constant symptoms of colica pictorum, and that by which the commencement of the disease is most clearly characterized. As to the circumstance so generally noticed by authors, of their being relieved by pressure, we find the following results from an analysis of the fifty-two cases which M. Grisolles has followed; viz. In forty cases the pains were relieved by pressure; in seven, pressure neither augmented nor relieved the pain; and, finally, in five cases the patient's sufferings were exasperated by pressure on the abdomen, whether moderate or powerful.

Retraction of the belly has also been described as a special symptom of the colica pictorum; however, it is not a constant one: thus, in forty-six cases in which the author sought this symptom with the utmost care, he found thirty-one in which the abdomen presented the ordinary volume and appearance; in fifteen only he found the abdomen retracted, and even in many of these cases

the symptom was so little apparent, that it required a good deal of care to determine its existence.

Nausea and vomiting are also symptoms which frequently exist. The author has observed them thirty-two times in forty-six; the matters ejected were always greenish, and excessively bitter; they bore no relation to the intensity of the disease, and seemed to be idiopathic, as they were removed by means directly addressed to the stomach.

The *slowness of the pulse* is also a symptom frequently noticed by authors. In the cases reported by M. Grisolles, the pulse varied between forty-eight and eighty-four, the first few days of the disease; and in all cases where the pulse was as low as forty-eight, the malady prevailed with great intensity.

The *pains in the genital organs*, which are more commonly situated in the tract of the spermatic chord than in the testicles themselves, were noted in a little more than one-fourth of the patients. When pains existed in the extremities, it was the lower which were most frequently affected (three-fourths to one-half), while in one-third of the patients the loins were the seat of pains not dissimilar to rheumatic ones. The headache was always of short duration, and was noticed only nine times in thirty-seven cases. In the seventy-eight cases of colica pictorum analyzed by M. Louis, the proportion is somewhat less, being about one-sixth. (?)

Epilepsy is one of the most grave accidents that can arrive during the course of colica pictorum, but it would not appear that it is a frequent one. The author observed only two cases in his fifty-eight. The disease appeared suddenly, and carried off both patients after thirty-six hours. Paralysis also appears to be a consequent of rare occurrence.

The march of colica pictorum is very irregular, but its termination is in general favourable. The want of accuracy prevents us from giving any faith to the results noted at *La Charité* by MM. Gardane, Merat, and Duchesne. In the fifty-six cases of the present thesis only two died, as we mentioned, from a sudden attack of epilepsy. The intestinal canal in these two was examined with the utmost care, but no trace was found of abnormal coloration, softening, or hypertrophy of the tissues. The cerebral convolutions were generally flattened, and

the anfractuities nearly effaced: the consistence of the brain was diminished throughout, but there was no trace of injection or of serous or sanguineous effusion in any part of the nervous centres.

The treatment of the colica pictorum has been various. That employed in the greater number of cases recorded by the author was the method so universally known as "the treatment of La Charité," and which consists in giving opium with purgatives, by the mouth or rectum. The purgatives, however, are what we in England would call laxatives; thus the lavement most commonly administered was—

R. *Decoction of Senna* ℥ij; *Sulphate of Soda, Mercurial Honey*, aa. ℥ij; *Water* q. s.

These lavements were administered alone, or combined with opium, to sixteen of the patients, of whom seven were affected with the disease in a very intense form. During the course of the disease, which on an average lasted five days and a quarter, they took six lavements, and five grains of opium. The other nine patients were affected less intensely; they were cured in four days and a quarter each, and took about four lavements and three grains of opium. This latter remedy was never administered until the constipation had been overcome, and the patient already more or less relieved. In six cases purgatives were given at the same time by the mouth and rectum; under the latter form they produced more abundant evacuations and most relief; these patients were cured in a period of seven days and a quarter. Three different kinds of purgatives were employed, viz. castor oil, mixed with one to three drops of croton oil, and the *huile d'epurge*, a lead remedy. *En résumé* the patients thus treated by the evacuant method were cured in a period varying from five days and a quarter to eight days, the maximum of treatment.

Within the last few years M. Gendrin has energetically insisted on the value of sulphuric acid, both as a prophylactic against the colica pictorum, and as a remedy for the disease when fully established. However, the researches of M. Grisolle seem to throw more than doubt on the first of these properties. Thus at the manufactory of Clichy, the mean duration of the workmen before catching the disease, is seventy six, when they have not drunk the sulphuric tisan;

while those submitted to the prophylactic treatment of M. Gendrin, do not remain more than fifty days free. As to the comparative value of the treatment called that of "La Charité," and the acid treatment, it requires a more extensive comparison of facts than we as yet possess, to enable us to judge between them.

The Gums, with late Discoveries on their Structure, Growth, Combinations, Diseases, and Sympathies. By GEORGE WAITE, M.R.C.S.L. Longman, 1835. pp. 160.

THE principle of the division of labour has been applied to medicine from a very early period; in Egypt, Greece, and Rome, when civilization had reached a considerable pitch of refinement, besides physicians, surgeons, accoucheurs, rhizotomists, and pharmacopologists, *medici ocularii* and *medici dentarii* were found exercising their respective vocations with distinction. In the present day, the "world of man" has been mapped out into so many compartments, that it is, perhaps, time to inquire whether the division and dismemberment is tending; whether the great connexions of the whole are not broken up; whether the general laws which govern the inside, the outside, and every individual part of our frame, are not overlooked; and whether the influence exercised on organs by each other, and by external circumstances, is not forgotten; whether, in fine, the science of medicine is not sacrificed to a great many arts. One man pays particular attention to the stomach; another watches over the biliary secretion of the kidneys or the bladder; this takes the lungs under his especial protection; that counts the beatings of the heart, or regulates the workings of the mind; Mr. Alexander takes care of his Majesty's vision; Sir Charles Mansfield Clark waits upon the Queen; Mr. C. by some strange fortune humbugs the Royal ear; and Mr. D. puts in claims to perform the same kind of office to another section of the Royal Person, "*et adhuc sub judice lis est.*"

Interesting as an extended inquiry into the effects of the division of labour applied to medicine would be, we have here only time to point it out as worthy the attention of several ingenious gentlemen whose productions occasionally fall under our notice.

and convince us that as poets sometimes want a hero, so they often want a subject, at least "a new one."

We pass over Mr. Waite's rather fantastical application of an old doctrine concerning the four ages of man, and the seasons of the year, to the teeth, which would thus have their spring, summer, autumn, and winter; as well as his illustrative quotations from Sophocles and Pindar; and shall extract his "Synopsis of the Diseases and Morbid Alterations of the Gums."

Synopsis of the Diseases and Morbid Alterations of the Gums.

"Diseases produced by proximate causes.

"Infantile and puerile diseases of the gums.

"Abscesses, tumours, swellings, inflammations, morbid affections.

"Diseases produced by remote constitutional causes are, First, those from the effects of scurvy or from scrofula. Secondly, from constitutional irritation, when neither scurvy nor scrofula has developed itself. Thirdly, from fevers, from indigestion, from catarrh, from inflammations. Fourthly, from mercurials. Fifthly, from constitutional debility, however induced, including nervous excitement and the passions of the mind.

"1st. Diseases produced by scurvy are,

A turgescence of the gums, with a brownish appearance of their structure.

An inordinate detention of highly carbonized blood in their vessels, and occasional hemorrhage.

Diminished vitality of the capillary vessels.

Suppuration, with purulent discharge from the mucous surfaces of the gums.

"2ndly. Diseased appearances produced by scrofula.

An alteration of the glandular structure of the gum, with disease of the capillary vessels.

Detention of blood in the apices of the gums.

Morbid exudations from the surfaces.

An atonic state of their general circulation.

These diseased appearances being devoid of the brown colour perceptible in scurvy.

"3rdly. Diseased alterations from constitutional irritation, when neither scrofula nor scurvy has developed itself, are

General heat, irritation, and redness, fungous excrescences, and hardened ridges.

"4thly. Diseased alterations from mercurials produce

Increased glandular action and vascularity.

Foulness, languor. A slough of the capillary vessels.

Morbid sensibility. Hemorrhage.

"5thly. Constitutional debility, however

induced, including the various passions of the mind.

Atrophy and atony of the gum.

Absorption of the socket and recession of the gum.

Languor, and the same morbid sensibility as results from the use of mercurials."

Mr. Waite's remarks on false teeth merit attention.

"Another condition in which we must consider the gums is that into which they are often brought by the unrelenting work of the tooth-maker. A tooth may early in life have been pivoted, and perhaps have gone on twenty years with tolerable comfort. This is often so when the root on which the tooth is pivoted is sound and good. The case, however, now alters: the root becomes either loose in the socket or worn by the pressure of the pivot, and it is necessary to fix it in another manner. This is effected by means of a plate of gold stamped exactly to the shape of the vacant gum and adjoining teeth, round which clasps are worked. The best contrivances of this nature which we meet with are those worked for many of the eminent tooth-makers of London by Mr. Claudius Ash of Broad-street. Those persons who profess peculiar methods of fixing false teeth, and pretend that inventions belong solely to themselves, are generally the adventurers of the town. The great secret of false teeth consists in employing scientific manufacturers."

Mr. Waite's work displays a better knowledge of general physiology than is possessed by ordinary dentists, whose ignorance is generally as profound as their plunder is enormous.

Rust's Magazine, &c.

THE last No. (No. 2, Vol. 44) of this journal contains:—

1. Fragments from the note-book of a clinical lecturer. By Professor BENEDICT, Breslau.

2. Remarks on several of the Symptomatic Affections which coexist with increased sensibility of a portion of the Spinal Column. By Dr. ESS. (Continued from No. 1.)

3. Case of obstinate Retention of Urine, produced by Inflammation and Suppuration of the Prostate. By Dr. ANGERSTEIN.

4. Case of immense Lipomatous Tumour. By Dr. BENN. (With a plate.)

Although an attempt has been made by Mr. Green, at *St. Thomas's Hospital*, to render some account of the medical statistics of that institution, and an announcement of a similar attempt is made by Mr.

South, "of that ilk," yet we are quite certain that the example will rarely be followed, and that the statistics of our public medical charities will not be made public, until the management of those establishments is in new hands, which, thank God, it soon must be. We have been frequently asked by some of the principal surgeons in Paris, to point out any work or journal in which they might seek for accurate accounts of the number of patients treated in the London hospitals, the comparative mortality of each, in short, any statistical survey of their population; but we have as often been compelled to answer, that our surgeons are in general too much occupied in making money to attend to anything not immediately connected with that absorbing object. For ourselves, being convinced of the great benefit which may be derived by amassing together these statistical details, so as at length to form the basis of general deductions, we shall not fail to gather, from time to time, the valuable fragments scattered through our foreign contemporaries, and thus in some measure supply a want which had much better have been satisfied by our own countrymen.

1. PROFESSOR BENEDICT'S FRAGMENTS.

The first article we have to notice in the present No. of *Rand's Magazine*, is a kind of review of the surgical clinique at the University of Breslau for the years 1828 to 1833 inclusive. The number of patients treated during that period was 5712, viz., 2812 surgical, and 2900 ophthalmological cases; however, the number of the former selected for clinical purposes did not exceed 700, to whom alone the following observations refer.

LITHOTOMY.

This operation was performed during the six years, thirteen times; once on a girl of twelve years; the rest on males, the oldest of whom had reached the age of fifty-three. All these patients were cured, with the exception of four, none of whom died immediately after the operation. Thus one of these four, a boy sixteen years of age, had been dismissed cured from the establishment, but died eleven weeks after of typhus fever. The second died fourteen days after

the operation, when the left kidney was found in a state of suppuration, and the right one engorged. In the third case, death on the 11th day, evidenced suppuration of the left kidney, extending down to the pelvis. The fourth case was fatal on the fourth day from peritonitis. In reference to lithotomy, Professor Benedict relates a very curious case, which, on account of its termination, is worthy of record. The patient, fifty-three years of age, who had long suffered from symptoms of stone, was received into the hospital in 1816, but left it without an operation having been performed. After a lapse of twelve years the patient presented himself again, but during this time the calculus had acquired such a magnitude, that whenever the sound was passed between it and the bladder, it became locked. It was thought scarcely possible to remove the stone by an operation; however, this was undertaken, and the incision being prolonged considerably towards the rectum (which was not injured), the calculus was extracted after its outer shell had given way under the forceps. The stone weighed seven and a half ounces, without counting several fragments that were lost. On the fifth day the patient was seized with low typhus fever, without any signs of inflammation of the urinary or abdominal organs. The usual stimulants seemed of no avail, when the author accidentally learned, that his patient was a confirmed brandy drinker. All other means were at once laid aside, and the patient given a *tablespoonful of brandy* every two hours. This treatment was followed by such happy results, that in four days the quantity of brandy could be diminished, and the patient was content with a glass at breakfast. The patient was discharged cured after some months.

LIGATURE OF UMBILICAL HERNIA.

This operation was practised twice, according to Dessault's method, within the period above mentioned. Although both cases were successful, the author says he would neither recommend nor undertake it again. In these, as well as in all the other similar operations practised antecedently, symptoms of severe inflammation of the abdomen set in after the third day, and were combatted often with very great difficulty. The author has frequently removed fungoid excrescences from the navel of young chil-

dren by the ligature (a disease frequently met with at the Clinique), without giving rise to any of the accidents before described.

STRANGULATED HERNIA.

Herniotomy was performed sixteen times in the period between 1828-33; five cases of inguinal hernia, two deaths; eleven cases of femoral hernia, four deaths. In most cases, the fatal result arose from gangrene of the intestine.

In one case of inguinal hernia, the patient was going on in the most favourable manner, when he was suddenly seized on the fifth day with trismus (in consequence of exposure to cold), and died in thirty-six hours. The autopsy did not afford any result.

In a case of femoral hernia in the female, the epigastric artery, which ran transversely over the sac, was divided. The wounded vessel immediately gave a strong gush of blood, and revealed the accident: the stricture was divided, as the author in the habit of doing in all cases of hernia, from below upwards, and from without inwards. The divided artery was immediately tied, but the patient died of gangrene.

AMPUTATIONS.

Amputation of the extremities was performed twenty-five times: of the upper arm five, one death; one case of medullary tumour of the fore-arm, cured; of the thigh fifteen, cures ten; of the leg four, two deaths. The amputation of the upper arm was performed in three cases after Almonson's method (the funnel-shaped stump); in the rest with a single flap; that of the fore-arm with a single flap; of the lower leg, the single flap; of the thigh, in three cases, with the double vertical flap; in one case with the single flap; in one by the circular method; and in the rest, according to Graefe's modification of Almonson's method.

CANCER.

The operation for cancer (not including cancer of the lip) was performed thirty-seven times. However, with the exception of one or two cases treated by arsenic and apparently cured, a radical cure was not obtained in a single case.

Extirpation of the breast was performed three times, and under circumstances apparently very favourable; in all the disease re-

curred again. Of ninety-eight amputations of the breast, which the author has performed since he undertook the charge of the clinique, two ended fatally from exhaustion during the healing of the wound; and in all the rest, with the exception of thirteen, the disease returned after the wound was healed, and terminated in death. With regard to the remaining thirteen, the author observes he is morally convinced that, in several cases, an error of diagnosis was committed, and breasts were removed that were merely affected with scrofulous tumours, sarcoma, or some other innocent change of structure.

The above results are worthy of serious attention, and serve, unfortunately, to confirm the opinion advanced by many surgeons, that in most cases cancer is a constitutional, not a local disease. After an investigation of a great number of morbid specimens of this disease, the author proposes to divide scirrhus into three kinds; viz., the lardaceous, the hydatiform, and the knotty scirrhus. Passing by the two former as sufficiently known, the author gives some remarks on the latter that are not without interest. This is a rare affection, and, on account of its march, is frequently confounded with a malignant and fatal form of scrofula. The patients are generally affected with small knots in one or both breasts, which do not enlarge during the progress of the disease. After these appear the ordinary tumours in the axilla, and at the same time we perceive ranges of small knots along both sides of the neck, tumours in the inguinal region, on the shoulders, and in several other parts of the body. Each of the knots now mentioned remains isolated, but approaches the skin, and finally becomes attached to it. The integument here assumes a hard, cartilaginous feel, is covered with varicose veins, and turns into a single small cancerous tumour. The patients now generally suffer under pectoral symptoms, with abdominal derangement, and in all the cases which occurred to the author, death took place in less than six months.

Cancer of the lip was removed in fifty-one cases, all successfully except one, where the patient was in a state of great weakness at the time of the operation. The author, however, regards it merely as a *palliative* operation, as it invariably returns in some other part of the body, or in the cicatrix itself. There are indeed a few cases in

which the tumour did not reappear, but here it was evidently a local disease, produced by some external cause, and not perfectly identical with the cancerous disease. As far as the author's observations extend, this false cancer is generally situated in the red surface of the edge of the lip, and does not pass beyond it, is more flaccid, and is chronic in its march; the sympathetic swellings in the neck are wanting. According to the opinions of modern surgeons, we may hope for a successful result whenever there are no tumefied glands under the jaw or in the neck; but from the author's experience, the absence of these signs does not justify a favourable prognosis. Either small soft tumours of the glands already exist, as may be discovered by a minute and careful examination of the parts in the neighbourhood; or the lymphatic system is implicated, without any actual enlargement of the glands, which does not take place until some time after the healing of the wound.

Our analysis shall be concluded in an early number.

Hecker's Annalen, &c. Vol. I. No. 4.

The last part of this periodical contains—
1st. Practical Remarks on Rabies in Dogs, Horses, Sheep, Pigs, &c. By Dr. WAGNER.

2nd. Practical Remarks on the Use of the Exhausting Pump (Lingpampe) in Strangulated Hernia. By Dr. KOHLER.

3rd. On the Literature of the Venereal Disease. By Dr. HACKER.

2. REDUCTION OF STRANGULATED HERNIA BY THE EXHAUSTING PUMP.

The use of the air-pump, as an agent in the reduction of hernia, was first noticed, we believe, by Professor Hauff in the year 1818. Hufeland's Journal for July 1832 also contains some remarks by Dr. Busch on the same subject. Finally, the No. of Hecker's Journal now before us contains several cases, which, as they are probably new to our English readers, we shall notice briefly.

Case 1.—In October, 1833, the author, Dr. Kohler, was called to a Jew, sixty years of age, who had suffered for the last nine years from scrotal hernia. After some days of a fit of indigestion the patient began to suffer from pain in the abdomen, and the hernia could not be returned even by a surgeon; the symptoms were now rapidly aggravated, and the author on his arrival found the patient in a state of great danger. According to the account of his attendants,

the hernia was strangulated for three days; the face was now sunken; the body covered with a cold sweat; the extremities cold; the pulse barely perceptible. No stool for the last three days. The author had immediate recourse to all the common remedies, venesection, cold applications, narcotics, enemata, baths, drastic purges, &c., without any effect; the danger was most pressing, and nothing seemed left but the operation; however, the exhausting pump was tried as a last resource. Immediately after the application of the apparatus, which was placed over the abdominal ring, the operator began to perceive some gargouillement in the hernia; this gave encouragement, and in a short time, to his great pleasure, the parts were restored to their natural position. Alvine discharges were obtained in a few hours, the vomiting ceased, and the patient was restored to health in a few days.

Case 2.—In January 1834, a female, sixty years of age, was affected with inguinal hernia on the right side, and sudden femoral hernia on the left side; it was impossible to return this latter; symptoms of strangulation soon set in, and the necessity of an operation was agreed on in a consultation of surgeons. The air-pump was applied. After the first application a little gargouillement; after the second, partial return of the gut; after the third, complete reduction of the hernia.

Professor Janekowski has communicated a very remarkable case to the author, of which the following is an abstract:—

Case 3.—The patient, a strong healthy woman, fifty years of age, perceived the first trace of an umbilical hernia about two years before. The tumour had acquired some size before she experienced any remarkable symptom; it was then partially reducible, and the pains in the abdomen and swelling were alleviated by opening medicines. After the lapse of about a year the tumour became suddenly the seat of intense pain; there was obstinate constipation for six days, which only yielded to general blood-letting and purgative enemata. On the sixth day inflammation set in, and terminated in abscess of the integuments. At the end of August the patient was attacked a second time with inflammatory symptoms, which now assumed so severe a character as to threaten her life with imminent danger. The hernia could not be reduced by any of the ordinary means, though seconded by venesection and repeated purgative glysters. On the third day the tumour became excessively painful and hard, stercoral vomiting supervened, and a fatal termination seemed almost inevitable. The air-pump was now applied, but at first produced a great deal of pain; however, it was removed after a short time,

and the taxis was now practicable with the greatest facility. In a few hours copious evacuations were produced, the symptoms of strangulation subsided, and three days later the patient was perfectly cured.

In addition to the cases which we have just quoted, the author details six others, where the air-pump was employed with equal advantage, and adds that in twenty-three cases, the greater part of which were desperate, the means now alluded to did not fail to justify his confidence; he therefore concludes, by expressing a hope that a remedy of such power may meet the general consideration which it deserves.

3. LITERATURE OF SYPHILIS.

This is an analysis, completely in the laborious German style, of all that has been written on the venereal disease during the years 1831 and 1832. The works of authors which are analyzed (alphabetically arranged) amount to no less a number than fifty-seven, and the series is not yet completed. Those who occupy themselves specially on syphilitic diseases will here find a fund of curious, and no doubt useful, information, for not one has been neglected.

FORMATION OF AN

EASTERN PROVINCIAL MEDICAL ASSOCIATION.

ON Friday, the 25th inst., a meeting was held at the Guildhall, in Bury St. Edmunds, for the purpose of forming a society under the above name. Upwards of seventy gentlemen of the profession, from Suffolk, and the adjoining counties of Cambridge, Norfolk, and Essex, were present.

Dr. PROBART, of Bury St. Edmunds, took the chair, and said that the meeting originated in the published letter of an influential individual now present. The call had been responded to in a most gratifying manner, and there could be but one opinion as to the general utility of such a Society. Resolutions had been prepared, and he should be happy to hear the remarks of those gentlemen to whom they were equated. He concluded by reading the resolution.

Mr. CROSS, of Norwich, addressing the chair, said that he was the individual who had been induced to set on motion the simple means for bringing them together. (Applause.) It was easier to follow than to vent. Above a dozen years ago was form-

ed "An Association of German Naturalists and Physicians," which first assembled at Leipsic, and changing annually the place of its meeting, visited Berlin, Vienna, Heidelberg, Frankfort, Hamburg, and some other towns of note. These annual scientific meetings had continued uninterruptedly—the last having been held in the present month, with undiminished gratification, at Bonn; and they had, undoubtedly, conducted greatly to the improvement of the natural sciences, of which medical men were always found the most zealous promoters. Numerous learned men from this kingdom, including many eminent physicians and surgeons, had annually attended the meeting of the *German Association*, and, amongst the fruits of that intercourse, we might trace the origin of *The British Association for the Advancement of Science*,—a society first instituted about four years ago at York, successively holding its annual meetings at Oxford, Cambridge, and Edinburgh, and terminating the brilliant work of its fifth meeting lately in Dublin. It would seem that this Society was destined to raise the character of our countrymen throughout Europe; it had increased in numbers, and still more in beneficial results, yearly; and had, indeed, spread a fresh ardour in the pursuit of science throughout the British dominions. The proceedings of its medical section at the recent meeting, so fully recorded in the last number of the "Dublin Journal," had brought much dormant talent into activity, whilst the funds of the society had been liberally voted to physiological researches, determining questionable points, and establishing facts that come home to every well-exercised practitioner, by bearing directly on the diagnosis of certain diseases. Out of the *British Association* another had arisen, which was exclusively medical, but embraced a less extent of district—the *Provincial Medical Association*, instituted at Worcester in 1832, through the efforts of Dr. Hastings, and a valuable volume of transactions had appeared yearly from it, the fourth being now in the press, forming the only series of transactions devoted to medical topics that had ever been published in England out of the metropolis. This Society enrolled 500 members, but having originated in the West, it had failed to enlist many gentlemen in this eastern and remote district, although intended to apply to the whole kingdom. The proceedings, said Mr. C., of the meeting at Oxford have been so amply reported, that every gentleman now present must be acquainted with them. Before I attended that meeting I had avowed my opinion, that the eastern counties should join to form a Medical Association on an extensive scale; but difficulties surrounded the attempt, a gentleman in this county having already made a fruitless attempt. Yet there is a conviction

amongst us of the necessity of taking some such step; few of us can so far desert our avocations as to meet the Provincial Association at the large towns of England; but we are social and scientific; therefore must we have our *Eastern Association*. (*Applause*.) In the six adjoining counties there are about a million and a half of inhabitants; yet not more than a few cases in the course of each year are turned to advantage through the press in the whole district. In the counties referred to, only a few medical men, I feel assured, belong to any Medical Association, and, judging from the effect of the associations preceding us, one in this district must bring forward the hidden experience of many, and awaken into fresh action and energy a valuable body of labourers in the calling we profess. The medical statistics of each county will furnish much matter. Medico-legal science may be promoted by close attention to inquests. The district contains many hospitals and dispensaries, and reports of the practice of such institutions will be for the first time produced. Every man of experience in practice meets with something that might prove profitable, if communicated to his brethren. During my twenty-five years' residence amongst you, I have known many enlightened, able, and zealous practitioners in the most retired situations. The association we are met to form may gather a storehouse of public knowledge. Moreover, assemblies of gentlemen of our profession generate kindly feelings, promote good understanding, and console us in our solitary hours. Thanking you for a patient hearing, I leave in the hands of other gentlemen the moving of the several resolutions. (*Applause*.)

Dr. PROBART said the meeting was greatly indebted to Mr. Crosse for his able address.

Dr. EVANS said he would only remark that the formation of such a society must prove highly beneficial to the profession and the community. He, therefore, proposed, "That a Society, consisting of Physicians, Surgeons, or General Practitioners, residing in the counties of Cambridge, Essex, Huntingdon, Lincoln, Norfolk, and Suffolk, or in other parts of the kingdom, should be and now is established, to collect useful information in medicine and its collateral sciences for publication, to maintain the respectability of the profession, and to promote a friendly intercourse and communication between its members."

Mr. ABBOTT, of Cambridge, seconded the resolution. The Society, he said, would peculiarly gratify him by bringing gentlemen into friendly intercourse with each other from different places. Carried unanimously.

Mr. JEAFFERSON of Framlingham proposed, and Mr. PECK of Newmarket seconded, "That an annual subscription of

one guinea be contributed by each member, to be paid in advance."

Dr. BAINB commended the alacrity with which the case made out by Mr. Crosse, who had so eloquently addressed them, had been responded to; it was high time that provincial medical gentlemen should strive to become more useful to the profession. Being, generally speaking, as it were, *rari nantes in gurgite vasto*, they laboured under the disadvantages of a want of co-operation; but he hoped that henceforth their medical character would be redeemed in the eyes of the public. He begged to propose, "That the Society do publish, in the form of Transactions, all such essays, memoirs, cases, or reports of public institutions, sent to them, as may be thought worthy of publication."

Dr. FISHER, of Cambridge, seconded the resolution. Carried unanimously.

Mr. HORRITT, of Yarmouth, proposed, "That a general meeting be held annually at one of the principal towns of the counties specified in the first resolution, and that the first take place at Ipswich on the first Monday in June, 1836."

Dr. ENGLAND, of Norwich, seconded it, and said he fully coincided in the principles of centralization; he thought that strenuous efforts should be made to improve medicine in the eastern provinces, or, as railroads were becoming so general, we might soon expect to see patients travel by steam to consult the physicians of other places.

Dr. FISHER thought the time specified would be inconvenient to residents at Cambridge.

Mr. CROSSE said it had been selected with a view to accommodate the profession in general. He thought the general meeting ought to take place *prior* to that of the Provincial Association, at Worcester, because a deputation could then go from the branch to the parent institution. (Carried unanimously.)

Dr. WAYTE congratulated his brethren on the object of their meeting, and especially on the opportunity that would thus be afforded of defending their rights and privileges. He was not a general practitioner now, but he had been, and therefore could enter into the feelings of those gentlemen on this subject: their calling was laborious and arduous, and they were often compelled to sacrifice their own health and comfort for the good of others. That profession was not only now invaded by both itinerant and regular quacks, but more recently by acts of Parliament—the Commissioners under the new Poor-Law Act, aiding the overseers to grind the medical man to powder. (*Applause*.) He thought the profession justly entitled to the protection of the Government—let them meet for that specific purpose—let them *petition*, and he had no doubt their voices would be heard by the Legislature. (*Applause*.) Why also should there not be

stars in the Eastern as well as in the Western hemisphere? He anticipated great good from the Society, and concluded by moving,—"That a Council, composed of not more than one-fourth of its members, do conduct the general business of the Society, and meet in Norwich quarterly, or more frequently, as the business of the Society may require."

Mr. BAILEY, of Thetford, seconded the resolution. (Carried unanimously.)

Mr. WAYLEN, of Colchester, proposed—"That a president, two vice-presidents, a treasurer, and a secretary, be annually elected, and be members *ex officio* of the council and of all committees."

Mr. CREED, of Bury St. Edmunds, seconded the resolution. With reference to a recent act of Parliament invading the just rights of the profession, he thought there was nothing to fear from that quarter. Let the physician, the surgeon, and the general practitioner, adhere to each other, and they had nothing to fear. (Applause.)

Mr. HEADLEY, of Cambridge, believed it was not the wish of the Poor-Law Commissioners to make degrading proposals to the profession. He knew one of them (Mr. Leffevre) and had had conversations with him on this subject, from which he was induced to believe that the fault rested rather with the overseers and guardians of the poor. (The resolution was carried.)

The appointment of officers for the next meeting at Ipswich was thus fixed:—Dr. Baird to be president; Mr. Crowfoot, of Beccles, and Mr. Bullen, of Ipswich, to be vice-presidents; Mr. Crosse to be secretary (and also treasurer *pro tempore*).

Dr. LYNN, of Woodbridge, proposed and Mr. HEADLEY seconded,—"That the council do assemble at Norwich in January next, to receive the names of members, and to consider all papers &c. which may have been communicated to the secretary."

Dr. BECK proposed, and Mr. MINES, of Diss, seconded,—"That a committee of five be appointed to draw up a code of laws and regulations for the Society, to be laid before the general meeting at Ipswich, and to make out a list of the first members of the Council."—The following gentlemen were then appointed as a committee:—Dr. Bayne, of Bury; Dr. Beck, of Ipswich; Mr. Dalrymple, of Norwich; Dr. Wayte, of Lynn; and Mr. Bailey, of Thetford.

Mr. MACINTYRE proposed,—"That a committee of five be chosen to prepare a plan for effecting a junction of the present Society with the Provincial Medical Association, instituted at Worcester, and to submit it to the general meeting at Ipswich." This embraced, he said, one of the principal objects of their association. A district like this would not be able to furnish funds sufficient to enable them, for instance, to publish annually such transactions as a photo-

rias as were necessary to promote a scientific interest in the Society. By joining with the Western Association, they might effect this object, and be put in possession of the "Transactions" of that Association.

Mr. LE NEVE, of Barrow, seconded it. He conceived many advantages would be derived by the Society from an amalgamation with that at Worcester.

Dr. FISHER wished to know whether, after such an "amalgamation," this Society would exist as a separate society.

Mr. WAYLEN considered it would be an auxiliary of the parent institution.*

Dr. EVANS said he understood that the two societies would be fused into one. He was a member of the Worcester Association, and he thought that members of that association, ought not to be called upon to pay two subscriptions; though, for himself, he would cheerfully pay two or more if they pleased.

Mr. CROSSE said the two societies would, in the appropriation of funds, be in common; in annual meetings they would be separate, excepting when the Worcester Association came into their district, and the same would be the case when their Society went into the other district. For the publication of all transactions and other useful purposes, the junction would be principally effected.

The following gentlemen were then appointed as a committee, in accordance with the resolution:—Dr. Haviland, of Cambridge; Dr. Baddeley, of Chelmsford; Dr. Nunn, of Colchester; Dr. England, of Norwich; and Mr. C. Smith, of Bury St. Edmunds.

Mr. MURIEL, of Ely, proposed "That an advertisement of the acts of this Meeting be circulated in the Eastern Counties, accompanied by an address calling the attention of Practitioners towards the support of the Society." (Seconded by Mr. Beddingfield.)

Dr. BECK proposed that at the next annual meeting, the Society should consider the propriety of engraving a Provident Society on the Association. (Seconded by Mr. Abbott.)

Mr. MACINTYRE said that he was impelled to meet it with a direct negative. The proposition was not compatible with the objects of this meeting; appeared to be wholly impracticable; must involve an increase of subscription not at present contemplated; and in his opinion was unequalled for. In counties which it was proposed their association should embrace, there were al-

* The ninth resolution was well calculated to puzzle the meeting. It seems to have been forgotten that the affiliation of the "Eastern Society" is the act of the wrong institution. Suppose the "Western Society," on whose funds a demand is to be made, should refuse to patronise the infant?—ED. L.

ready societies existing, and some of them—he could speak for that of Suffolk—though not so well supported either as they deserved to be, dispensing great relief. He would recommend that instead of attempting to form a Benevolent Society, those gentlemen who had not joined the excellent societies in their respective districts, should take the first opportunity of doing so.

Mr. ABBOTT said that they had no such society in Cambridgeshire.

Mr. MACINTYRE was sure that Mr. Abbott might soon have one there.

Dr. EVANS concurred in the objections of Mr. Macintyre, and the sense of the meeting being against the resolution, Dr. Beck withdrew it.

Mr. CROSSE said it would be desirable that papers or reports intended for publication, should be forwarded as early as possible to the Council to be held in January next. Votes of thanks to Dr. Prohart and Mr. Crosse were then carried with acclamation.

THE DINNER.

Fifty-six of the gentlemen afterwards dined sumptuously at the *Angel*, when Dr. PROHART again presided, having for his vice-presidents Mr. C. Smith and Mr. Macintyre. Dr. EVANS afterwards took the chair. Various toasts followed the loyal ones. Dr. EVANS proposed, amongst others, the University of Cambridge. Dr. FISHER returned thanks, and passed some high compliments on the present Regius Professor of Medicine, Dr. Haviland, whose absence he much regretted. "The health of Mr. Crosse and thanks to him for his great exertions in forming this Association," was drunk with warm applause. Mr. Crosse acknowledged the compliment.

Mr. MACINTYRE said that there was a gentleman present to whom the profession were under considerable obligations, and who had been instrumental in the formation of this society; he deserved their consideration, not merely as a talented member of the profession, but for the able stand which he had made against the grinding system of contract recommended under the New Poor-Law Bill; and he (Mr. M.) was happy to have that opportunity of putting them in possession of the information which Mr. Bedingfield had collected on the subject. "The health of Mr. Bedingfield, of Stowmarket."

Mr. BEDINGFIELD, in returning thanks, said he came that day to be a hearer rather than a speaker; but he would, with permission, say a few words. All the time he could spare from professional engagements, had been occupied in defending the profession from the unjust aggressions of the Poor-Law Commissioners. The question, said Mr. Bedingfield, has been put to me several times to-day, What should we do relative to the contracts for attendance on

the poor? I will tell you, gentlemen, what we have done in our own Hundred. My colleagues, Mr. Spencer Freeman and Mr. Bree, joined me in an address to the Directors and Guardians, expressive of our wish to remain in the same situation as we at this time occupy; we requested that we might not be compelled to enter into engagements which it would be impossible for us conscientiously to perform, and that if any parishes were added to the Hundred of Stow, other surgeons might be appointed to them. My address to Lord Melbourne was followed up by some strong observations in the House of Commons by Mr. Wakley, to whom in my opinion the medical profession is most deeply indebted. Mr. Wakley, in powerful and eloquent language, set forth not only the inconveniences to which medical men are subjected by the arrangements made under the new Poor-Law Bill, but also the miseries which would be inflicted upon the poor themselves, by that oppressive measure. Lord John Russell is reported to have stated in reply "that he had been assured by the new Poor-Law Commissioners, that they had provided the poor with ample medical attendance." One fact in my own immediate neighbourhood, shall serve to illustrate the tender mercies of these commissioners towards the poor. The Hundreds of Bosmere and Claydon consisted of thirty-five parishes; to these parishes four surgeons were attached; the Poor-Law Commissioners have added five parishes to this hundred, but they have only provided the poor with three surgeons! and so exquisitely judicious are their arrangements, that the poor of the populous Hamlet of Needham will have to go to Coddendenham for their attendance, and one of the surgeons will have to ride from Needham to Debenham, a distance of ten or eleven miles, to visit his patients: all further comment upon this subject is unnecessary. I have been asked what we shall gain by opposing the commissioners. If I am correctly informed, we have already gained one important advantage. The power of appointing and determining upon the number of the surgeons, and the amount of their salaries, is taken out of the hands of these commissioners, and is vested exclusively in the local guardians. A very interesting communication was made to me a few days ago by Dr. Rumsey, of Chessham, in Buckinghamshire, informing me that a society had been formed in Buckinghamshire, of which Dr. Rumsey was President, for protecting the profession. Here, gentlemen, is an organized committee ready to receive any facts that may be adduced to elucidate the oppressive nature of the new Poor-Law Bill; and to arrange these facts, and to submit them when thus arranged, to the consideration of the proper authorities. Our society is not prepared to perform this important business; I would therefore

earnestly recommend you, gentlemen, to forward all the facts you can procure upon this subject, without loss of time, to Dr. Ramsey. I have put my hand to the plough, and I will not look back; but heedless of intimidation and slanders, I will still advocate the rights, honour, and interests, of my professional brethren. (*Applause.*)

Mr. Crossk read an extract from a letter he had received from one of the principal Commissioners, which stated that they (the Commissioners) had no desire to interfere with, or direct the contracts between, the parish authorities and their medical attendants.

The company were afterwards addressed by Dr. England (who warmly eulogized the efforts in Parliament of Mr. Warburton), and other gentlemen, and the party broke up about ten o'clock, highly gratified with the prospect of accomplishing the object which had brought them together.

SUICIDE BY THE ADDER.

To the Editor. SIR,—An adder was captured by me and confined very loosely in the folds of a thin lawn handkerchief, so that I might observe its efforts to escape. The handkerchief was laid with the adder on a grass plot, and after several energetic but ineffectual attempts to free itself from bondage, the animal deliberately inflicted a bite on its own body, and quickly died. Such an act of suicide has been asserted of the scorpion, but I have never heard of the like circumstance in an adder, excepting on this occasion. The circumstance cannot be attributed to *instinct*, a principle which might assist it in its efforts to *escape*, but could never prompt so unnatural an act as that which produced *death*. Let this fact (witnessed by two others as well as myself) be added to the number of extraordinary events which foil the philosopher in his efforts to deny the existence of intellect, unquestionably bestowed in various modifications on the lower animals of the creation. I am, Sir, yours truly,

WILLIAM H. THOMAS.

Bristol, Sept. 16, 1835.

BIRMINGHAM SCHOOL OF MEDICINE.

LETTER FROM DR. CONOLLY.

To the Editor of THE LANCET.

SIR—In your remarks on the Anniversary Meeting and Dinner of the Birmingham School of Medicine, in THE LANCET of Sept. 12, it is stated that I proposed as a toast the "Theory and Practice of Medicine." The erroneous statement, con-

ating with the reporter of the *Birmingham Gazette*, would be quite immaterial, but for the manner of its introduction in support of some not undeserved censure. I trust, however, you will permit me to say that I proposed no such toast. I was requested to acknowledge the honour done to myself and the other examiners; and having done so, it was my duty to name and propose the healths of the gentlemen to whom medals had that day been awarded. The only other toast which I proposed was the health of Mr. Cox, senior, the father of Mr. Sands Cox, to whose exertions the Birmingham School of Medicine is so greatly indebted.

Although it may add a little to the length of this communication, I cannot refrain from giving, on this occasion, my sincere testimony to the proficiency, as far as I had an opportunity of judging of it, of the students of the Birmingham School. I have occasionally thought that the apprehensions expressed by some of my seniors in the profession, that the education in provincial medical schools would be found superficial, were not unreasonable. But I am convinced that they are unfounded. The utmost care seems to be taken to make the students well informed in every branch of their profession. The two students who presented themselves as candidates for the medal in Dr. Eccles's class, that of medicine, were subjected to a *viva-voce* examination, about an hour and a half being devoted to each; and their answers were so satisfactory as to make it impossible for me to doubt that they had been well taught both in the lecture-room and in the hospital. A student's proficiency is, of course, only to be looked upon as an earnest of future diligence and usefulness; but, seeing the number of provincial schools now established, it is gratifying to believe that they will tend to increase the number of well-informed practitioners. My opportunities of forming an opinion, when in London, of the knowledge possessed by students from the schools of Manchester and Bristol, had previously inclined me to take this favourable view of the provincial institutions; and whoever looks at the rising provincial museums, must see that every year adds to their efficiency as places of instruction. I am, Sir, your very obedient servant,

J. CONOLLY.

Warwick, Sept. 25, 1835.

LITERARY INTELLIGENCE.

MEDICAL REFORM IN IRELAND.

We have not yet received a copy of the work mentioned in the following letter, but, as a preliminary step to its introduction to the profession, we do not know that we can furnish a better announcement than

that which the letter of Mr. Phelan becomes by its insertion in our columns. The letter was not, we believe, designed for publication, but a very useful purpose may probably be served by letting the able and industrious author speak for himself in this stage of the affair.

To the Editor of THE LANCET.

SIR,—Hodges and Smith, of Dublin, who have lately published a work for me on the medical charities of Ireland, with suggestions for a medical poor law for their better regulation, are about to send some copies of it to London, and I have directed one to be sent to you, as a mark of my respect for the many services you have rendered the medical profession as well in Parliament as out of it.

Should you have leisure to glance over this "Statistical Inquiry," I am not without hopes that you will see in the effort an anxiety to be useful; and that the number of facts and returns which I have collected, and put on record, will strike you as tending to give a more rational view of the state of our institutions.

You will observe that all the information is that obtained by a private individual,—often got from persons most unwilling to give it, and, in some cases, after having left home, and the professional business depending on being at home, in search of it.

But still I have endeavoured to expose errors and abuses, whilst retaining whatever is valuable in our charities,—and by such exposure, feeble and imperfect as it is, some good may and, I hope, will be done; but that entirely depends on those who are induced to read it, or to adopt the doctrines which it advocates, and who possess the power of giving effect to such opinions as I

have offered. I trust it will obtain the favourable consideration of the medical reviewers in London, and, amongst them, whose influence as a journalist is so extensive as is yours.

You have no idea of the difficulty of reforming the medical profession, or the medical institutions, of Ireland,—so great is the influence of the Dublin Colleges, and so deeply imbued with the spirit of Toryism are the governors of the hospitals &c., in numerous places. Nothing but the enactment of a well-digested and most searching law can have any effect in rendering our charities what they ought to be, a blessing to the poor, and a benefit, indirectly, to the rich and to the medical profession.

I would particularly request attention to the sixth and tenth chapters, and shall be most anxious to learn if the plan on which I have proposed that a combined hospital and dispensary system should be conducted, meets your approval. I also beg to draw attention to the appointment of inspectors, and to the proposal to publish a statistic medical report annually, or occasionally. In this *land of jobbing* the exposure from inspectors is particularly necessary, independent of the other advantages which they would afford.

Apologising for occupying so much of your time, I remain, Sir, your very obedient, humble servant,

DENIS PHELAN,
M.R.C. Surgeons in London.

Colonel, Sept. 22, 1835.

Mr. WARDROP has in the Press a work "On Bloodletting, being an account of the Curative Effects of Bleeding in the Treatment of Disease." It will be published in a few days.

LECTURE

INTRODUCTORY TO A COURSE

ON SURGERY

DELIVERED AT THE ALDERSGATE SCHOOL OF
MEDICINE, OCT. 4, 1835.

By MR. SKEY.

GENTLEMEN,—It will be my duty in the ensuing course of lectures, to point out to you the means which we employ, in either curing or alleviating those diseases which custom has allotted to the care of the surgeon.

I presume I need hardly tell you, that these diseases are for the most part external; yet they follow that general rule not unexceptionably, or, rather, there exists a sort of neutral ground on which the external region of the surgeon is met by the purely medical treatment of the physician. I will not dilate on this topic, because it necessarily follows from the present system of practice, that the large majority of my auditors comprises the future practitioners of all classes of disease; and between myself and the accomplished physician on whom devolves the task of instruction in the department of medicine in this school, there need be no jealousy, no rivalry or difference of opinion, as regards the extent or boundaries of our respective duty. One thing is certain, viz., that the ground-work is the same, that however apparently various or distinct may be the structure, the proximate cause of disease, with some modification, is the same; and the principles of treatment can therefore but slightly differ. The practice by manipulation is, however, the exclusive province of the surgeon, and this includes the extensive and highly important department of operative surgery, which, if any, presents the most eminent characteristic of surgical practice.

A course of lectures on surgical science admits two very distinct objects of study; the first comprises the principles which guide us; the second, the application of

those principles, known under the term of practice or treatment; and on these two subjects I beg to engage your attention for a few minutes. By principles, we understand general rules, which, although modified by circumstances, are applicable to all similar examples of disease. The principles which govern practice are based on a knowledge of the great functions of life, both physical and moral; namely, physiology; but surgery demands the knowledge of the anatomist, by which alone we can detect deviations from healthy structure; and without which we cannot advance one step towards their removal. In speaking then on the subject of the principles of surgical practice, I return to those of anatomy and physiology. The first tells us the situation, form, relation, and structure, of every part subject to disease. Physiology expounds their healthy functions, and their mutual dependence on each other: we must be conversant with both. With respect to anatomy, then, how can the man who is ignorant of the healthy appearance of the human eye, determine its diseased condition? How will he distinguish the extent to which that delicate membrane the iris deviates from health, who is ignorant of its healthy or normal appearance and character? How will he be enabled to pass a needle into the interior of the globe, for the purpose of displacing the opaque crystalline lens, in cataract, if he be unacquainted with the size, form, and connexion of that body? Look at the numerous forms of accidents attending joints, and say if it is possible that the man who is ignorant of their natural form, and the connexion of their parts, can determine on the one hand, or attempt to remedy on the other, the accidental injury they have sustained.

There are, however, doubtless many surgical diseases, the treatment of which may be effected, without any immediate reference to the science of anatomy; but is there any that does not bear, more or less, immediately on that of pathology? Certainly none. Take the simplest form of surgical disease, an ulcer. By what means is its progress arrested? We know that in the condition of health, the arterial circulation of a part should remain steady and unexcited; its

temperature cool and uniform. We find it hot, red, painful, and the vessels are unnaturally distended with blood; they relieve themselves by pouring out matter; the skin bursts; the unhealthy condition of the vessels remains; the surface fails to heal, and an ulcer follows, for there is a variety of ways in which such a malady may arise. How shall we determine the treatment? We observe the character, whether inflammatory or otherwise; we reduce the undue action of the vessels by such remedies as experience has taught us are beneficial; and, having accomplished this, we proceed to another stage of the treatment, which consists in urging nature to heal the wound. In the attempt to avert or cure disease, the importance of this branch of physiology is inestimable; I would say it is the ground-work of all medicine,—in its most comprehensive sense, a knowledge of the principles of life.

Nature has endowed the organized world both animal and vegetable, with a principle which cherishes growth and which presides over every action of which its organization is susceptible. The same spirit, jealous of defect, controls disease, repairs injury, and by its continued influence tends to maintain the outward physical form, as well as to repair the inward defect of function to which the frame is liable. It has been called the *vis medicatrix naturæ*. In the language of the Latin poet,—

"*Spiritus intus alit, totamque infusa per artus*

Mens agit molem et magnæ corpore mæcet."

It consists in an evident and universally acknowledged effort on the part of nature, to ward off disease and to preserve life. "A spirit of health" predominating over the body, ever rejoicing in its salubrity, ever contending against injury. Need I illustrate it by examples? They are endless in variety. Why does an abscess invariably advance towards the surface, but for the purpose of discharging its contents without injury to the body? The liver would appear to possess discrimination in evacuating the contents of a similar disease through the abdominal parietes, in preference to the cavities of the abdomen and chest, to which it would have nearer access. In tubercular abscess, the large vessels of the lungs are as it were, incrustated with lymph, lest their rupture should be fatal to life; and this effort is especially beautiful, inasmuch as the disease itself is necessarily fatal in its termination. For here we see the contention most vividly between an irremediable disease and the unremitting effort of this "spirit of health."

In the disease of bones, how beautiful, how varied are the exertions of this protecting principle, in which a bone is destroyed by a wasting disease, arresting all chance or power of reparation,—during the process of

destruction, a new pillar is in process of erection by which the diseased fabric is fortified, and the limb restored to health and action! Observe the structure of artificial joints, or those from which the cartilage is absorbed; here we see the respective ends of the bone or bones, carefully rounded off and polished, to simulate as much as possible the original structure. The formation and increase of large aneurysmal sacs; their temporary protection from rupture by the dense layer of coagulum by which they are lined; their evident desire (if I may so express it) for contraction and subsequent obliteration;—the contraction of the divided ends of large arteries;—the formation of accidental bursæ, for the protection of the subjacent bone, whenever the skin is subjected to continued pressure or friction;—the almost dental hardness of the gum, consequent on the loss of teeth, and the approximation of the teeth on the loss of one or more;—the inflammatory and lupus-effusing condition of a wounded intestine, by which its injured surface becomes agglutinated to the parietes of the abdomen, or to another portion of intestine, thus closing the otherwise fatal aperture;—the really astonishing co-operation of this healing, this protecting influence, with the hands of surgeon, in transmitting the contents of the intestine, along a devious track, in artificial anus, from the upper to the lower opening, and the subsequent earnestness with which the margins of the bowel unite for the purpose of restoring the integrity of the canal. Observe the analogy in this respect of vegetable to animal life. Plants are provided with muscles, by which they open and shut their flowers, and turn their leaves to the sun, even if they have been repeatedly folded back from it; the turn of a hop plant is invariably directed towards the course of the sun, and it soon dies if artificially forced into an opposite line of growth; remove the obstacle, and the plant quickly returns to its former position. When the straight branches of the honeysuckle can no longer support themselves, they acquire strength by becoming spiral; when they meet with other branches of the same kind, they coalesce for mutual support, and one spiral turns to the right, the other to the left, thus increasing the probability of their finding support by the diversity of their course. If a plant be placed in a room which has no light, except from a hole in the wall, it will shoot towards the hole, pass through it into the open air, and then vegetate upwards in its natural direction. The shoots or tendrils of creeping plants, are invariably directed towards the nearest object to which they cling, and the direction of a tendril may be repeatedly altered, by changing the position of the object attracting them. From these, and a variety of similar evidences of spontaneity, it has been inferred that vegetables have a limited degree of sensation.

and enjoyment, and that they have an inferior participation in the common allotments of vitality.

I might cite endless examples of Nature's anxiety to maintain health, by throwing off disease or obviating deformity. Now, where does this power reside? In what does it consist? The advance of time had made considerable encroachments on the eighteenth century, before the antiquated doctrines of the chemists and mathematicians succumbed to the more just and reasonable views of the *vitalists*. For this revolution we are greatly indebted to *SPALL*, who was forcibly impressed with the difference between the changes which the components of the body experience during life, and what would occur in the same substances under other circumstances; hence he concluded that when they form a part of a living system, they must be possessed of some additional principle, that counteracts the effects that would otherwise be produced. To the agent that thus opposes the physical powers of matter, and to which the body owes its vital properties, he gave the name of *anima*. He considered it to possess powers of a specific nature, and attributed to it a species of intelligence which enables it to act the part of a rational agent, and to superintend all our corporeal operations. *VAN HELMONT* applied to the same principle the term "*Archæus*."

But what are we to understand by these terms? The immediate nature of this principle, or the mode of its operation, we are totally ignorant of. It is sufficient for our present object that we acknowledge its existence, observe its influence, and obey its dictates.

I say emphatically, *obey its dictates*. We talk of many diseases in a tone of arrogant defiance of the very laws which direct our every step. Take a wound for example. The utmost limit that the surgeon can advance to, is that of bringing the margins in close contact, and keeping its surface clean, and where he fails in this end, nature is compelled to come to our assistance, and heal by new substance what with a little extra aid she would have accomplished with much more ease and readiness. What is the extent of the boast here? That of an humble and almost powerless assistant; and thus it ever must be. We must ever continue humble followers in the path of nature, and dependent on her bounty.

The first part of my duty here, then, as our instructor, is, to disabuse your minds, directing your attention to that influence and authority which you *do not possess*. She is imperative; she is arbitrary; her laws are immutable; she will sustain no interference, and listen to no compromise. This I conceive to be the first, and most paramount concession to her power, demanded of the practitioners of our art.

we enter on our task prepared to watch and to obey. Let us then study her peculiarities, and, as far as possible, imitate her example. It will thus be my wish to inculcate a simplicity of practice, in which consists the only true philosophy of the art of healing. We are the sappers and miners in the forces of nature. We attend her path with the view to remove obstructions—to cleanse impurities—and having accomplished this, to leave her unmolested and uncontrolled. If I dwell on this subject, it is because here I would place the gravamen of a charge against those members of our profession, who, wanting a firmness of reliance on the authority of nature, or patience in its application, intrude upon her path with an unseasonable and officious zeal, perverting her energies by the application of means subversive of her most obvious intentions.

To Mr. *ABERNETHY*, whom I am proud to have called my friend as well as my instructor, the profession owes a debt of gratitude for enforcing, both by his precept and by his example, the value of this all-important principle. "*Subdue local irritation*," says he, "and regulate the action of the digestive system, and you control all controllable disease." To him it appeared (how is it surprising that it should have done so?) the philosopher's stone of medical practice; and if I express my regret that his application of it should have been so universal, I am bound to declare that within the circle of my experience no man was so successful in the controlling influence over chronic disease as he.

I say again, study nature, assist and second her intentions, but do not attempt to lead her. The influence of remedies for the most part is but negative.

These primary principles admitted, we proceed to the theory or principles which more immediately influence our treatment. I have already stated them as "general rules, which, though modified by circumstances, are applicable to all similar examples of disease." Now there is an obvious distinction between the theory of a disease and its treatment. By theory we understand the contemplation of, the reflecting or reasoning upon, a subject. This one would suppose an essential prelude to the treatment of all maladies, but it is not really so, inasmuch as the principles of life, or, rather, the views and objects which nature may have in contemplation in the cure of any particular disease, may not be so obvious as to obtain the unanimous concurrence of all physiologists. They may be susceptible of various explanations; whence the number of irreconcilable views taken by different authorities; and, as regards many diseases, their treatment was adopted on unknown or ill-understood data, and numerous theories have been based upon them, to suit the prejudices of their numerous inventors.

There is a natural and well-grounded prejudice against what are called *theorists*. The tendency of a man's mind to theorize is, *ceteris paribus*, just proportionate to the activity of his imagination, and as nature has so ordained it, men's judgment is ordinarily defective, as their imagination or love of speculation is acute. Thus it is that minds naturally imaginative, whose flight of thought equal in celerity the movements of the playful Puck, "who could put a girdle round about the earth in forty minutes," and whose speculations cost them neither time nor labour, see through the mysteries of diseased action, trace the movements of the master mind that wills it, "and give a local habitation and a name" to the self-created authorities of their ill-guided imagination. It is not from men so gifted that our profession will derive much advantage or instruction. Pray you avoid them.

There is another class of men, the objection to whom is so closely associated with the preceding, that I cannot forbear alluding to them,—they are mathematical surgeons. A man's mind that has been long accustomed to direct and palpable evidence, and whose conclusions are inevitable, though the very reverse of the imaginative, endeavour to reduce the question of principle to the level of direct reasoning, who will believe nothing that he cannot explain upon the same irrefragable principles of reasoning, as lead to the positive deductions of mathematical science. The tone of mind which this study engenders, appears to me not the most desirable for a practitioner of our art, notwithstanding the immense advantages which it affords in invigorating the reasoning powers. I should be sorry to be supposed desirous of withholding my tribute of admiration for highly cultivated intellect or reasoning power; but I assert, that so long as the data are but imperfectly known or understood, and until the principles of life and the nature of their operation are brought within the grasp of our comprehension, that that man's practice must be (to use the mildest term) most imperfect, who would postpone for one hour the application of a remedy, because he could not explain the rationale or the principles of its action; and there are too many practitioners of this class.

With the action of how few of the innumerable remedies of our Pharmacopœia are we thoroughly acquainted! This may be deemed a species of empiricism, but within a certain restraint it is essential to every practical department of our profession. You must not expect, then, that you are entering on a study, the principles of which can be reduced to a course of reasoning as certain and as conclusive as that of mathematical science. Empiricism means practice. It consists in the application of remedies which experience has taught us the value of, but

which we have obtained through any means but those of reason. Take, for example, the treatment of some forms of disease of the testicle. We find them essentially benefited by the use of emetics. What is the rationale of this? Does the disease depend on a morbid condition of the stomach? If so, a form of aperient that would relieve it of its contents in common with the whole of the intestinal canal, ought to accomplish the same end, but it does not. Local depletives, aperients, diaphoretics, are equally inefficient, and an emetic finally removes the evil. Now the stomach and the testicle have neither vessels nor nerves in common. It is referred to sympathy. Is this satisfactory? To me I confess it is not, and in the state of our knowledge I should largely prefer acknowledging my entire ignorance of the *modus operandi* of the remedy, than I would mask the real difficulty by a pretended explanation, that would never be borne out by close physiological investigation. The conviction of our ignorance is the first step towards the improvement of our knowledge.

But, in the mean time, shall we withhold the emetic till we can explain the phenomena of its use? Certainly not; therefore the practice by empiricism is a necessary part of our duty. The late Dr. Gooch, the most able and most amusing lecturer of his day, was in the habit of recommending to his class some forms of medicine, which comprised a combination of a large variety of medicines in a single dose. In commenting on this "mess," as he was accustomed to denominate it, he used to say, "I combine these medicines together, because I find them answer the object I have in view; I do not attempt to explain the theory of their application; but I find them useful, therefore I employ them." With regard to this subject let me observe, that the chief object of my reference is, that I am desirous that you should not commit yourselves to an explanation of the *modus operandi* of a remedy, unless you see its operation clearly and distinctly. Its consideration will conduce to a most important end,—that of leading you to *reflect and reason*,—to establish, as your groundwork, clear comprehensive premises, on which your treatment is based; to eschew the jargon of words with which the really ignorant man involves in a mystery of technicalities the statement of his opinions, and to endeavour to trace the workings of disease by simple and concatenated steps to their ultimate termination. I attach the highest value to that instruction which teaches simple principles,—which places before the eye of the student the first processes of disease. I should be content rather, were he about to abandon instruction, to place him in the path of improvement, having adopted simple and distinct, but intelligible views of the early stages of disease, than I would endeavour to explain the

interest or his attention by vivid descriptions of extensive and uncontrollable disease. I should prefer to study nature in a case of common ulceration, in which my assistance might be valuable, to pursuing the endless ravages of a malignant growth, of the nature and source of which I may be totally ignorant, and in which the only advantage I could confer, would be sympathy for the sufferer. And here let me advert to a common error among students, which owes its existence to a defect in their education,—that of misnaming cases of disease by the application of the epithet “good.” You hear that Mr. So-and-so has a “good case” in such a ward, or “a good case of accident has just come in; they are gone for the surgeon to cut his leg off.” Gentlemen, these are not good, but “bad” cases,—bad in every application of the word,—bad as regards the patient, for his body is mutilated by the knife,—bad as regards the art, for they justly expose it to obloquy,—and bad as regards yourselves, for they afford you no knowledge beyond that derived from beholding a painful operation, which you may possibly witness for the first and last time in your lives. I conceive a good case to be susceptible of relief or cure, and then the more extensive the malady, the greater the “goodness,”—a case in which the art of the surgeon triumphs over disease, efficiently co-operating with nature in its eradication,—not one in which the surgeon takes the case into his own exclusive charge, and effectually extirpates it by the amputation of the limb of which it formed a part.

Now, Gentlemen, if for the purpose of warning you against unphilosophical and unreasoning views, of exposing to you the real level of our knowledge, and of preparing you for the necessity of availing yourselves of the aid of remedies, the action of which in the present state of our knowledge admits of no satisfactory solution, I have for one moment become the advocate of empiricism, I trust that the principles of education I have subsequently advocated, will guarantee to you my conviction of its utter incompetency to advance professional knowledge. Empiricism may be employed as the refuge, without being the cloak, of our ignorance. It may prove a valuable resource. It may temporarily represent, it can never supersede, the practice of reason. We may employ it as the homage due to the unexplained mysteries of nature; but it must ever be deemed a detracting blot on the real dignity and intellectual rank of our profession.

Having considered the principles of practice which are so immediately founded on a knowledge of the principles of life, I come to the subject of *treatment*, or the application of remedies. Now without dilating on their various classes, whether medical or manipulative,—whether direct or indirect,—

whether local or general, I conceive that next to the knowledge of their mode of application, the most important rule I can insist on, with certain limitations, is the necessity of their being restricted to a degree of activity inferior to that of the disease they are intended to control. This I believe to be an important principle of treatment, which I can best illustrate by example. A man rises in a morning after healthy sleep, his intellect clear and vigorous, with the circulation in his brain light and free, *because* during sleep his brain has been subject to a fuller access of blood, by which his mental faculties have been temporarily superseded.

The return of the circulation to a part of the body that has been exposed to excessive cold, is succeeded by a degree of heat above the surrounding temperature, and productive of a tingling pain. On the same principle we are told that a warm-bath is the best protection against the intensity of summer heat. These I may call phenomena of health. The same holds with regard to disease. Headache and throbbing are frequent consequences on fainting, in which the brain sustains a temporary loss of its circulation, and this, whether from loss of blood, or from a shock to the nervous system, producing the same result.

If you arrest any unhealthy secretion by a too powerful stimulant, the secretion returns in quantity proportionate to the activity of the means employed.

The means usually resorted to in the acute stage of gonorrhœa to suspend the discharge, most frequently increase the disease.

If you employ moderate pressure on the surface of healthy granulations, you increase their energy and promote their growth; small doses of aperient medicines, taken at certain intervals, will tend to constipate the bowels. In like manner stimulants, whether medical or moral, are succeeded by depression proportionate to the activity of the means employed.

All this is explained on the *principles of reaction*,—a principle so important and so universal as to influence our treatment of almost every disease.

For the purpose of maintaining growth, and of affording nutrition to every part of the body, of invigorating it by adding new materials to its structure, and of removing those which are superfluous or old, and consequently useless, nature has established the circulation of the blood. But for the purpose of controlling its irregularities, she has placed it under the superintendence of what is termed the nervous system, connected immediately with the brain or spinal marrow. These two agents, then, concur in the production of almost every description of disease. We cannot except from this law even the diseases of the circulation itself, which owe their origin to a defective state of the nervous system. How far we

may give to the nervous system an independent authority in the production of what are termed *neurasthenias*. I shall not now stop to inquire; there is a difference of opinion on this subject; but we must consider these two phenomena as intimately, and almost indissolubly, connected in the performance of the various functions of life; if the circulating system be in immediate dependence on the nervous, in accomplishing the design of its creation, in no less a degree is the nervous tributary to that of the circulation, for its force and energy.

The term "irritation" expresses a local disturbance of the nervous system, which is generally followed by a corresponding derangement in the circulating system, and inflammation is the result. If the irritation subside, the vessels resume their natural condition. Now I may define *reaction* to be the rebound of the nervous system after the application of any means that have tended to excite or depress it.

Let us imagine that nature has provided this system with great dormant power, beyond the necessities of the daily functions of life, which is only called into action on great emergencies, and we shall see why this rebound exceeds considerably in degree the condition in which it was first found.

What is the explanation then of the various phenomena I have alluded to? Exposure to the cold produces contraction of the vessels, by depressing their nervous system; the cause being removed, the vessels do not return to their former condition of healthy action, but are stimulated by the unhealthy rebound of the nervous system to undue action, in which the nerves themselves participate.

The warm-bath, by promoting the cutaneous exhalation, and raising the temperature of the surface, excites the circulation, which by the same rebound maintains a lower temperature throughout the day.

Fainting produces headache, by the reaction of the vessels of the brain, consequent on inanition. The application of a powerful stimulus to a secreting surface, excites the vessels to contraction, through the medium of their nervous system; this condition remains until they recover from the shock, when they pour forth their contents, with a degree of violence far surpassing their former condition; here I am, of course, supposing the stimulus to be considerable.

The application of slight pressure to healthy granulations, promotes their growth by simple excitement, that of a foreign body. The pressure tends to diminish them, and their increased growth is the necessary consequence: if the excitement be too great, the granulation is absorbed; and this object, where the granulations are of an unhealthy character, is often most desirable. Small doses of aperient medicines exciting in too slight a degree action of the intestines, sus-

pend their natural and healthy functions by the same principle of reaction, and if renewed at comparatively short intervals, will suspend the action of the bowels entirely. The nervous system, in its moral sense, is subject to the same laws and is productive of the same consequences, whether in its normal or morbid condition. Excessive joy is invariably attended by painful depression and distress of mind, be the stimulus moral or physical. The mental anguish which overwhelms the drunkard, is not solely referable to the stings of conscience; while the furious and intractable hallucinations of the maniac, gradually sinking into exhaustion, exhibit him melancholy in spirit and powerless as a child. To uphold the physical and moral frame, and to maintain it in the condition of the fullness of health, the circulating and nervous systems must possess a uniformity of action, and an identity of power. They rise and fall together; they are indissolubly united. If you reduce the circulation by the abstraction of blood, to the same extent you lower the tone of the nervous system. How strikingly is the intimate and mutual dependence of the two systems manifested by the experience of every day! How entirely does the energy of character sink under the wasting energies of the bodily frame. Observe the labouring man! with limbs of giant mould, and the vigour of whose constitution and his endurance of pain appear to set at defiance the invasion of disease; subject him to the consequences of repeated abstraction of blood, or lay him up for six weeks, contending against continued irritation from a compound fracture, and his energy of character is gone, his intolerance of bodily pain is converted into sensibility the most acute; he becomes puerile, fretful, and suspicious. And will not in like manner the momentary blush of shame, or the rapid and irregular pulsation of the heart under the influence of fear, with equal force denote the dependence of the circulating on the nervous system? This intimate dependence must ever be kept in view by the practitioner. It may serve to teach us, that however extensive may be that class of inflammatory disease which warrants the abstraction of blood from the circulation, we cannot exceed the quantity which the most judicious observation would point out, without committing a double wrong.

In proportion to the excess of force in the remedy employed, will be the consequent *reaction*: may I not therefore with reason, insist on the importance of that law, which restricts the activity of our remedies, and which renders them efficient only when employed with a degree of force inferior to that of the disease they are destined to remove?

With regard to the immediate subject of remedies, they are either internal or external, the latter being local or general. *Alia*

may divide the internal remedies into those which give vigour or frequency to the circulation, and those which diminish its force. Now in the medical treatment of disease, doubtless the latter largely predominate: of these, the most efficient is that of blood-letting; a remedy calculated to accomplish the greatest good, and susceptible of the greatest ill.

Unfortunately, perhaps, it is a remedy always at hand; certainly it is employed with great effect, and often with great advantage, but that its agency is largely abused I have not the smallest doubt. There is no part of the treatment of disease which demands clearer perception and nicer discrimination, than the distinction between that condition of the circulating system, which either foretels or is actually attendant on inflammation, and that which denotes the excitement of the same system from weakness. Of all parts of the body, there is none which possesses so strong a claim on the circulation of the blood as the brain. On the abstraction of any considerable quantity, the brain appears to yield to the general amount of loss, a less proportion than any other organ or part. If you bleed an animal to death, the vessels of the brain are found distended with blood; as though that organ presided over the body as the primum mobile of its action. Throbbing of the vessels of the brain, however violent, is *more frequently* an exhibition of irritation or weakness, than of inflammation, indicating that the balance of the circulation is suspended, and that the brain is asserting its claim to a too large proportion of the residue to be compatible with its just and healthy distribution. The abstraction of a large quantity of blood cannot be justified at the hands of the surgeon, excepting for the purpose of contending against positive inflammation. I have no idea of taking blood for the purpose of reducing a patient's pulse to a certain standard. I have no idea of taking blood to avert a possible, nay, even a probable attack of inflammation; nor is that practice in any degree more warrantable, that would extensively reduce the circulating fluid, to the end of diminishing the force of muscular contraction. Unless the nervous system be cognizant of disease, you cannot take blood with impunity; and the same quantity of blood that might be advantageously drawn, under real and positive inflammation, might be fatally drawn without it. Nor is this principle exhibited only in reference to the abstraction of blood, but it appears, with the same force, to every operation for the removal of a disease, which, as I have before expressed it, the nervous system is not cognizant. These observations will, I apprehend, be found most especially to apply to patients of what are called an excitable nervous system, and to females of marriageable life. I will give

you an example: during my residence in Paris in the year 1829, I witnessed an operation by Baron Dupuytren, for the removal of one of the breasts of a young woman, not from disease to observe, but because its position was such with regard to its neighbour, as to impair the symmetry of her foot. She suffered severely during the operation; inflammation did not succeed to an extensive degree, but she died, apparently from the shock her nervous system had sustained. Within a few weeks of her death, a second case occurred precisely similar in all its important particulars; after being at the verge of the grave for many days, this girl subsequently but slowly recovered.

I remember to have witnessed an operation for the removal of an innocent tumour from the shoulder of a young and susceptible woman, who, like the preceding, suffered greatly during its performance. There was something about her constitution that assured me there was danger attendant upon it. She died within three weeks of the operation, without the occurrence of any considerable degree of inflammation to which to refer it.

I remember another patient, a female, who died after the slight operation of removing a diseased bursa from the surface of the patella. Now in none of these cases was there any pain, and little inconvenience. All these persons were in rude health, and the rude health destroyed them, because their nervous system sustained a shock for which it was totally unprepared. I might dilate on this part of my subject with advantage, but you possess the opportunity of hearing these principles enforced by his authority, to whom the profession owes much of the merit of their promulgation.

Another observation on the general subject of remedies, is that of their peculiar action on different constitutions. Mr. ANERSTHY was accustomed to say, "All medicine is an experiment; what agrees with one man may not agree with another." We are all acquainted with the existence of certain idiosyncrasies as they are called. Some persons are severely salivated by a single grain of mercury, others are overwhelmed by small quantities of laudanum; and the repugnance to ipecacuanha is quite remarkable in some constitutions. I am myself acquainted with the wife of a medical man, who experiences a most distressing sensation whenever the stopper is removed from the bottle of that drug, even in another room. All this tends to enforce the importance of the maxim I have endeavoured to insist on—namely, the importance of restricting the quantity of the remedy applied.

The foregoing observations I am desirous of applying to treatment, or the use of remedies, internal or external, and for the

most part medical. There is, however, a second division of this subject which yet demands our consideration, and that is the manipulative. This comprises the reduction of dislocations—the setting of fractures—the determining by the touch, or local examination, the presence of fluid—indeed it includes the whole circle of operative surgery. In some form or other it must come within the experience of all of you, and though many may never possess the opportunity of acquiring the experience of operators of the highest class, yet it is impossible that you can avoid some intimacy with this important branch. Now there appertains to the public an opinion of our profession (than which none can be more erroneous), that to perform with the highest efficiency the duties of operative surgery, a surgeon should pursue his path indifferent to the wants or feelings of those whom either disease or accident has consigned to his charge. But they form this opinion, from the apprehension of an extreme of opposite evil—that of failure, *during an operation*, of the fortitude of the operator. Is there no medium? Is harshness or indifference the sole alternative to that unstable condition of the nervous system, which would endanger the life, or enhance the misery of our patient by failure in decision? Of the two I should deem the former the greater evil, for it pervades the whole conduct of the man. It extends to the deprivation of mental relief in no less a degree than it exhibits an indifference to his physical pain. I consider the sufferings of a patient as likely under many circumstances to obtain more probable mitigation from the sympathy of his surgeon than from his judgment. Doubtless the constant access to the exhibition of serious injuries may tend to render, in some degree, callous, the natural impulses of a sympathizing mind; but to the same end that delicacy of touch is essential to the detection of some forms of disease, so in delicacy of perception and susceptibility of feelings can the mind exhibit those endless resources which real and disinterested sympathy alone could invent and apply to the relief of the sufferer. It may be truly affirmed that the touch of the surgeon exhibits the character of his heart, and it is remarkable how striking is its exhibition.

Many diseases may be detected by delicacy of manipulation, which may really pass unobserved under a coarse and violent effort made to expose them. How often do we see men seize on a fractured leg and shake it with positive violence for the purpose of enabling the bystanders to hear the crepitus caused by the friction of the fractured ends of the bone; or, in cases of compound fracture, in which the finger is coarsely thrust into the external wound with a view to determine the direction of the fracture (a piece

of most unimportant information probably), or of scraping away with the nail any comminuted portions of bone which must escape by a later and more salutary process! Some men can never see a wound without ramming in a probe, or a director; and all these persons pursue their wanton career, equally regardless of the sufferings of their patient and of the principles of their profession. But the cultivation of this delicacy of touch is no less a matter of duty, than of policy. Its presence is, in the majority of cases, the most direct path to the confidence and to the approbation of our patient, who relinquishes his case unreservedly into our hands, persuaded that the amount of pain he may sustain no art could have diminished. But it is not only as regards manipulation, but in the exercise of those numerous and highly appreciated personal attentions, the surgeon may rely with confidence that his services are esteemed, and will be liberally rewarded.

Gentlemen, at the bed-side of your patients you will learn the practice of surgery. It is not only with your finger on the radial artery that you will fully comprehend the characteristics of a *full*, a *hard*, a *frequent*, or an *intermittent* pulse,—for they are all relative terms,—or that you will discriminate the various degrees and stages of fever dependent on local injury. The practice of your profession cannot be learnt from lectures, the chief object of which is principle. What do you imagine to be the comparative advantage derived from one glance at that form of inflammatory tumour which we term a carbuncle, and that obtained from the most elaborate description by the lecturer; why, in the one case the disease would be immediately recognised; in the other, the student would doubt its identity until he had referred to some more competent authority.

I remember an example of an industrious and intelligent student whose attention I directed to a case of aneurysm. He thought himself familiar with the disease, but with the case before him he was compelled to acknowledge his ignorance, declaring that it had little resemblance to the malady his imagination had pictured. The eye is the most perfect of all the senses, and least liable to imposition. It will embrace and transmit more knowledge in a single minute, than a lecturer could dictate in an hour. The whizzing sound of an aneurysm, or the peculiar and indescribable sounds of a diseased heart, can only be appreciated by the ear. The condition of an abscess, the thickness of an aneurysmal sac, the temperature of the skin in fever, or the peculiarities of various and uncertain diseases of the vessel and its membranes, can only be determined by touch; and what description, precise and admirable though it be, can supersede the office of the eye in determining

ing the position of a fractured leg, or the infinite varieties in the aspect or expression of countenance in a patient passing through the changes from disease to health. At the same time I do not wish to impress on your minds the belief that lectures are useless. Considering them as the *only* source of medical instruction, I think them useless; but they must be viewed as forming a part of instruction, and a part only. Unless the knowledge there acquired be confirmed by its application, it will form but a useless compound of undigested material which could merely qualify its possessor for commencing the study of *practical* surgery.

I cannot conclude this introductory lecture without directing your attention (not for the first time, however, I believe) to the necessity of cultivating some qualities, without the possession of which you cannot hope, whatever success may attend your path, to possess your own self-esteem, or that of your professional brethren. It is most wonderful, how little reliance can be placed on the simple statements of professional men. They appear to see everything with a jaundiced, or at least a prejudiced eye. If he relate a successful case, its peculiarities are almost instinctively magnified, for the purpose of exciting admiration, or obtaining approbation at the success of his treatment.

All speculative men have some theory to support, or some views to maintain, to which the symptoms and circumstances of the case are made to bend. They enter not on the consideration of their subject with minds simply animated by a love of truth; or, rather, the love of truth is overwhelmed by that of some more paramount thing; but men appear desirous to obtain a fictitious importance, by identifying themselves with something wonderful, — something uncommon and beyond the reach of others; this is not honest. The fact is, that the line which circumscribes the boundary of truth is perfectly defined, though easily transgressed; and so prone are we to deviate beyond it, that its barrier ceases to become an obstacle in our path, and is trampled, unheeded, underfoot, becoming more and more indistinct, until it is a positive effort to detect it. Thus truth is confounded with fiction, and the narrator can only obtain the credit of his auditors to the extent of truth, by a compound increase in his deviation from it. There is, there can be, but one course which a perfectly honourable mind will pursue, and that is neither to amplify or embellish, but to adhere to the strict letter of truth.

This was the course adopted by one among remarkably few exceptions to the general rule. I mean Mr. Hey of Leeds, whose single unsophisticated mind, eminently distinguished for its *love* of truth, combined with remarkable talent for observation, afforded him the means of an unreserved communication with the progress of disease,

and to lay up an immense collection of important facts in reference to their treatment. I consider his works as one of the best models of surgical literature; not elegant, perhaps, but they possess an air of truth that should be doubly cherished, because, unfortunately, they stand pre-eminent in this particular. For requisites such as these, the graces of style, and the sacrifice of truth to a well-turned period, form but an indifferent substitute.

In conclusion, gentlemen, let me recommend a systematic pursuit of study, and perseverance in its acquirement. A few cases, say three or four, are amply sufficient to engage the attention of the early student, of which notes should be taken. These notes should be made in the most condensed manner possible, but should be at the same time comprehensive, because they should embrace all the important facts which really bear upon the case, and these only. Practice in this part of your duty can alone enable you to give effect to this most desirable system, by perseverance in which you will possess a text-book for your future practice. Let me assure you, in the words of Lord CLARENDON, "that there is no art or science that is too difficult for *industry* to attain. It defends us against all strokes and assaults of fortune. It is that only which conducts us through any noble enterprise to a noble end. What we obtain without it is by chance—what we obtain with it is by virtue."

CASE OF

ACUTE PHLEGMASIA DOLENS.

To the Editor of THE LANCET.

SIR,—The following interesting case occurred in my practice, and I beg to forward it to you for publication in your useful periodical. I have the honour to be, Sir, your obedient servant,

JOSEPH HODGSON, M.R.C.S.
Spitalfields, Sept. 22, 1835.

April 4, I was engaged to attend Mrs. Horner, of B. G., in her first confinement, which she expected would happen at about the end of June. Age 39; tall in stature; fair complexion; very irritable in temper. Says, in her own language, that she has had so many attacks of inflammation, that scarcely an organ in her body has escaped. Desired her to pay great attention to the bowels, which were inclined to be constipated, and to keep her mind as quiet as possible.

11. Has a severe attack of pneumonia, which required three bleedings from the

arm, leeches freely applied to the chest, and nauseating doses of *Ant. Tart.* and *Ipecac.*, before it was subdued. Blisters and expectorants restored her to health by the 28th. She went on very quietly until the

6th of July, when I was called to her at half past seven a.m., and before nine o'clock she was delivered of a full-grown girl.

7, 8, and 9. Symptoms favourable.

10. Complaints of sharp pain in the uterus; lochia suppressed; pulse 120, and hard; tongue clean; bowels open. The nurse says that these symptoms came on yesterday evening, immediately after she had shown a good deal of temper about a very trifling matter. Apply *Hirud.* xij to the part in pain, to be succeeded by fomentations and poultices. *Hyd. Sub.* gr. j; *Pule. Dorer.* gr. v, sextis horis sum. *Encina commun.* cras mane, si opus sit.—*Evening.* V.S. ad 3xx.

11. Rather easier; pulse softer; tongue clean; bowels open; blood of yesterday cupped and buffy. Contin. medicament.—*Evening.* Pain returned. Apply *Hirud.* xx to the hypogastric region.

12. Pain gone except on pressure; skin perspirable; tongue clean; pulse 115, and soft; bowels relieved by the enema. Apply *Hirud.* xij, and continue the medicine.

13. Passed a comfortable night; lochia returning; other symptoms as favourable as yesterday. *Tinct. Hyoscyam.* ʒj xxx; *Tinct. Digitalis* ʒj x; *Liq. Ammon. Acet.* ʒj; *Mist. Camph.* ʒx. M. f. haust. ter in die sumend. *Ol. Ricini* ʒss, cras mane.

14 and 15. Going on well, which she continued to do, except being annoyed by what she called "rheumatic pains in her hips," for which some anodyne liniment was ordered. I was making my visits rather far between, with the intention of leaving her, when I received a hasty summons on the 28th. Right leg and thigh twice the size of the left; tense, and exquisitely painful in the course of the femoral vein. Says that "she felt the pain and swelling gradually proceed from the womb into the thigh and down the leg." Pulse 115, and very incompressible; tongue remarkably clean; bowels confined. V.S. ad 3xx; apply *hirudines* xxx along the course of the veins, to be succeeded by hot fomentations and poultices. *Haust. Cathart. c.* *Pil. Cal.* gr. v statim sum.; *Pule. Dorer.* gr. v; *Hyd. Sub.* gr. j; *Extract. Hyoscy.* gr. v; *Ant. Tart.* gr. ʒ. M. f. pil. ʒj, 4tis horis sum.—*Evening.* Blood sily; pain diminished.

29. Pain returned; says "it is exertiating, particularly about the calf of the leg;" pulse 120, and very firm; bowels freely opened. *Venesectio* ad deliquium, which produced immediate relief. Contin. med. ut heri.—*Evening.* Pain returning: applicatur *hirudines* xxx. The thirty ounces of blood taken this morning were very much cupped, and very buffy.

30. Limb easy; skin moist; bowels open;

has slept four hours without waking.—*Evening.* Pain about the calf of the leg. *Applicatur hirudines* xx. Med. &c. ut heri.

31. Progressing.—*Evening.* Slight pain in the calf of the leg. *Applicatur hirudines* xij; med. &c. ut heri.

August 1. Passed a good night; leg and thigh quite easy; swelling subsiding; *Mag. Sulphat.* ʒj; *Infus. Rosæ* ʒxj; *Tinct. Hyoscyam.* ʒj x. M. f. Haust. ter in die sumend.

2. Leg and thigh rapidly decreasing; appetite good; allowed a generous diet. Med. and poultices to be continued.

3. Doing extremely well; pulse about 96; tongue, as it always has been, very clean. *Quinina* gr. ʒj; *Infus. Rosæ* ʒiss. M. f. Haust. ter in die sum. *Pil. Plummer.* gr. v omni nocte. *Ol. Ricini* pro re nata. Has nursed the whole of the time, and I am much astonished that she does not show the discipline she has undergone.

15. Patient gone on improving since the 3rd; appetite exceedingly good; bowels regulated; both legs of the same size; complains of weakness and pains in both legs; bandages to be well applied to the thighs and legs; recumbent posture for some time; and sent into the country.

Sept. 14. I hear that she is doing remarkably well; but, as she cannot walk much, she is very irritable. I think I may say that I never had a patient with whom I had more influence.

ULCERATION OF THE LARYNX.

To the Editor of THE LANCET.

SIR,—I beg to transmit to you the following case and observations for publication in your excellent journal.

January 6, 1834. Thomas W., residing near Middleton, was affected for a considerable period with soreness of the fauces, attended with difficulty of deglutition and hoarseness, and followed by pain on pressure over the cartilages of the larynx, or when that organ was forced from side to side. During these symptoms he was teased with a short dry cough. In this state he continued during several weeks, when the former symptoms became more aggravated, the cough being very troublesome, and attended by a fetid odour and purulent expectoration. He had been treated by several surgeons in the surrounding neighbourhood for consumption, but without benefit. When I saw him, he was much reduced in health and strength, and complaining of pain the larynx from pressure or motion, particularly in attempting to swallow. Deglutition, indeed, was very difficult, and quite impossible if the food was solid. The cough frequently expelled fluids through the nares or attempting to swallow them. There was

constant and profuse expectoration of fetid mucopurulent matter, sometimes streaked with blood. The voice was nearly destroyed, the respiration hurried and difficult, and the rale sibilant sometimes produced a whistling sound. Pulse 110, small and quick; skin dry; countenance anxious; tongue loaded and furred; thirst distressing. He has some desire for food. The bowels are natural. He rarely enjoys sound sleep. On looking into the pharynx and depressing the tongue, the epiglottis can be seen ulcerated at its apex, and the surrounding tissue is highly vascular. Previous to the disease in the larynx, he had enjoyed good health, excepting on contracting syphilis a few years since, not followed, however, by secondary symptoms.

I directed the ulcer to be touched with muriate of antimony, and ordered him to have sarsaparilla, broth, diet, and one-eighth of a grain of dento-chloride of mercury daily.

Jan. 19. He thinks there is less pain in the larynx. He dozes constantly. Ordered him a pint of porter daily.

26. He this morning coughed up a portion of bone, in form resembling the right arytenoid cartilage. His respiration is rather easier; in other respects he is the same.

27. He spent a bad night; occasionally raved; cold perspiration; pulse 120, and irregularly intermittent. Since the last report he has sunk very much. The pulse is scarcely perceptible; expectoration very difficult; he frequently mutters, and lies in a state resembling an imperfect coma. At eleven o'clock this evening he complained of weight and fulness about the heart, and in two hours after, expired without a struggle.

In the translation of Laennec's work by Dr. Forbes, Laennec remarks, that ulcers of the bronchia and larynx are in general found in subjects whose lungs are entirely sound; but in a note appended by Dr. Forbes, the opinion of Louis is given in opposition to that of Laennec, and Louis states, that ulceration of the larynx, and more particularly of the trachea and epiglottis, is peculiar to phthisis. From the cases which have occurred in my own practice, I decidedly hold the opinion of Laennec, and am opposed to that of Louis. I am in attendance at the present time on a lady residing at Blackley, near this town, who is labouring under ulceration of the larynx, in whom the sounds elicited by the stethoscope indicate a healthy state of the viscera of the chest, and such was the case in the subject above-mentioned.

I am, Sir, your obedient servant,

EDMUND TAYLOR.

Blackley, near Manchester,

Oct. 2, 1835.

CARBURETTED HYDROGEN.

[We received last week from Dr. Clanny a letter dated Sept. 20, in reply to the letter of Mr. Roberts which appeared in our columns. To allow this controversy to extend in *THE LANCET* one line beyond what strict justice demands to either party, is not our intention. We are not alone influenced in this determination by the fact that the cause of dispute is not clearly known to our readers. It must suffice then, on the present occasion, for us to insert the following abridgment of the statements contained in the first part of Dr. Clanny's letter of the 26th. The remainder of that communication is published entire.]

To the Editor.—Sir,—I request that you will be pleased to insert in your valuable journal the following letter from Mr. Newman, the celebrated philosophical instrument maker, in reply to a query addressed to him by me. The statement of Mr. N. goes to prove incontestably the correctness of all I have had occasion to write respecting the changing of the wire in my safety-lamp.

"122, Regent-street, London, 24th Sept., 1835.

"Dear Sir,—In reply to yours I beg to say that when your safety-lamps left my house, the metal cylinders which surround the wire-gauze were held up by pieces of fine brass wire passing across the cylinders. Part of a coil I found in your box, and which was returned. I had tried the experiment previously with some of the same wire, and found the flame of a candle sufficient to fuse it, which caused the cylinders (which were suspended by it) to fall, enclosing the wire-gauze.—I am, Sir, respectfully, your obedient servant,

JOHN NEWMAN.

"To Dr. Clanny, Sunderland."

As Dr. Birkbeck was not present in the room adjoining to the lecture room when J. Roberts placed the infusible piece of wire across the cylinder of my safety-lamp, he cannot with propriety assert that "it was an accident," and that "nothing unfair took place."

I beg to mention a few words upon what I called the sanction of the honourable Chairman for my withdrawal of my safety-lamps. The moment I saw Mr. Pereira drive the coal gas jet through the wire-gauze, I said (when I walked up to that part of the table on which the lamp stood), "I am satisfied that something wrong must have taken place, as such an accident as this never occurred before nor ever can again." I then deliberately used my glasses, and found that a piece of thick wire had been substituted; and upon removing my safety-lamps, I heard Mr. Upton, the partner of J. Roberts, very forwardly appeal to the hon. Chairman "whether I should not be compelled to submit my safety-lamps to Mr. Pereira's experiments." On removing my lamps, the

Chairman, Mr. Pease, M.P., put the following question to me; I give it as nearly as my memory permits. "Dr. Clanny, do you consider your safety-lamp as not having been tried, as it was not properly trimmed?" The impressive manner in which this question was put, called me from my seat to the table, when I firmly replied, "I do so consider it." No wonder, knowing what I knew and seeing what I saw, that, to use the words of Dr. Birkbeck, "I intemperately adhered to my decision, and refused further examination of my lamp." I have a letter from Mr. Pease, dated House of Commons, Sept. 5th, at the end of which that gentleman says, "Upton and Roberts asked me whether I had any objection to state my opinion that the mismanagement of the lamp was accidental. I had no hesitation to go so far, but I stated to them that your lamp had not been tried, because it was not trimmed as directed."

As to the "Medical Gazette," I shall not henceforth read one word in that periodical, even if it ever be edited by a gentleman.

Before I lay down my pen, I beg to make an observation on the subject of experimenting upon carburetted hydrogen, or, as it is now called, "bi-hyduret of carbon," which may be of service to those who may be inclined to follow up such experiments, and which I intended to have appended to my communication, inserted in THE LANCET of the 19th of this month. The graduated glass-tube, containing bi-hyduret of carbon and of chlorine in noted proportions, is to be placed upon the shelf of the pneumatic trough containing water, and the whole of the tube must be covered with a cap of pasteboard, or some such substance, so as to keep out the light effectually; but if the experiments be performed in artificial light, no such precaution will be needed. The mixture of gases must be left in a tranquil state for ten minutes, which will be a sufficient time for all the chloride of hydrocarbon, or oil-like fluid, to be formed. When we perform these experiments in open day-light, it (viz. the light) will accomplish the condensation of the olefant gas, with the formation of carbonic acid gas and hydrochloric acid gas. This experiment appears to be an easy one, but it presents difficulties in the execution which require particular exactness. Thus it is, that if the experiment be performed over pure unmixed water, a certain portion of chlorine gas will be absorbed, which will detract from the quantity of the chloride of hydrocarbon; and if we employ water saturated with chlorine gas, the olefant gas, in its passage, will produce a quantity of chloride of hydrocarbon, which ought not to be the case.

Last spring I printed a few copies of a small tract for private circulation amongst

my friends, containing some "new researches upon flame;" and since my return from London I have most diligently prosecuted the subject, and find that in respect to yellow or light-giving flame I was correct, but in other respects, having since had time to correct one or two passages, I now find no difficulty in making public my discoveries thereon. I hope in a few days to have the pleasure of transmitting to you an account of those original experiments; and am, Sir, your obedient humble servant,

W. REID CLANNY.

Sunderland, Sept. 26, 1835.

MALIGNANT CHOLERA.

To the Editor of THE LANCET.

SIR,—In the summer of 1832, when the cholera was devastating the Canadas, a tattered old man appeared in Montreal, whom the Catholic populace were induced speedily to canonize for his successful treatment of this disease, which was at that time almost as mysterious to the population as the stranger himself. To this modern saint vast numbers of the infected were brought, who were restored to health from the most violent attacks of the inflammatory stage, as well as the worst possible collapse, even after the duly authorized medical practitioner had exhausted and relaxed his efforts. The remedy consisted of a due admixture of maple-sugar, charcoal, and lard, which *mélange* was given to his patients in large quantities after every ejection. The results were astonishing, and could be indicated in the speedy alteration of the countenances of the sufferers, and the early subsidence of vomiting and purging.

We must not cry down this remedy as empirical, inasmuch as its merits appear to be effectually borne out by the employment of these agents, homely and cheap as they are.

It is obviously improper to permit a patient to continue retching when his stomach is in a state of violent inflammation, as in cholera, without a fluid or unctuous substance being interposed between the sides of the villous coat, to prevent attrition, and afford matter for expulsion upon which the antiperistaltic action of the stomach shall expend itself rather than upon its own substance. Unfortunately in the extreme was it for the patients of those who permitted not the use of any liquid but that spirituous poison which added fuel to the flame. Thus lard was combined in this remedy, not because it was the best, but the most common lubricating agent.

Mortification and gangrene are the consecutives of inflammation; hence it was thought necessary, in a disease which as

quickly displayed these phenomena, to apply a substance which should afford the best and most common antiseptic capable of being administered in bulk without the influence of any other qualities. This was supplied by charcoal.

Sugar, in common with lard and charcoal, possesses powerful antiseptic qualities, combined with a stimulating property; and in the addition of this constituent the necessity of a stimulus was acknowledged by the old man, in common with the medical profession at large, who have almost universally admitted that principle; but unfortunately the mass of the profession (at least in North America) could not admit the axiom without taking leave of their judgment, and administering spirituous liquors to excess, and, in consequence, many hundreds, to my knowledge, died in the same condition as they had lived,—namely, drunk. I must remark, in passing, that I consider the brandy and laudanum treatment, the unnatural combination of a narcotic and an inflammatory stimulant, to have been a stain on the intelligence of the profession, — a practice conceived in gross ignorance of the disease if not of the agents themselves. The main feature of cholera is inflammation of the stomach, for instance. I have seen no case in which congestion and inflammation of that organ have not existed. What, then, are the most proper applications to be made to it? for the stomach is in nearly the same circumstances as those of a limb suffering from phlegmonous inflammation. Administer substances which shall serve the offices of fomentations, poultices, and ointments. This may be derided as quackery, but we are bound in this disease to try every expedient which bears the remotest feature of a rational principle, or is founded upon any recognizable maxim.

I am bound also to state that *at the instant of attack*, a liberal bleeding, *but fomentations*, and the administration of ipecacuanha and antimony, have been successful with my own patients. I have, ever since I lost my first case (that of a companion and friend, by the abuse of laudanum and brandy), invariably used the hot fomentation, and no circumstance has occurred to stagger my faith in its efficacy. I am, Sir,

Your obedient servant,

W. H. THOMAS.

Bristol, Sept. 16, 1835.

SAFETY-LAMPS AND FIRE-DAMP.

To the Editor of THE LANCET.

—As some parts of Dr. Clanny's letters, which are not altogether personal, relate to his own opinion of the explosive quality of the fire-damp of coal-mines, and the power of safety-lamps to

prevent the ignition of that gas, I trust you will allow me, through the pages of your scientific and much-read publication, to point out some dangerous errors into which, I conceive, he has fallen. The subject is one of great interest to all well-disposed persons, and of immense importance to those who are engaged in coal mining—much valuable property having been destroyed, and hundreds of lives lost, even within the last two years, in all probability by the prevalence of erroneous notions on the subject. I certainly do not think that the tests to which the safety-lamps in the late trial were put were too severe. No test ought to be considered too severe that could be met by any lamp then produced. One of the objects of the Committee was to obtain the highest security for the miner that could be obtained in a lamp. Were they then to take lamps that were not even safe to the test of common coal-gas, when one could be found that would bear the test of hydrogen and atmospheric air?

Amongst other observations of Dr. Clanny is the following:—"Had Sir H. Davy, in his admirable experiments on the inflammable gases of coal-mines, found any gases stronger than the fire-damp or light carburetted hydrogen, he would have no doubt so modified his wire-gauze (without using the *objectional* medium of glass), that even jet of coal-gas could not by any chance be driven through it." * * * "All these experiments of Mr. Pereira (therefore) go for nothing, as our pitman can testify." Now, with respect to this modification of the wire-gauze in the Davy-lamp, or in any lamp on its construction, any pitman will readily testify, and with good reason, that this modification of the wire-gauze has been carried to the full extent in all such lamps, which will leave them in any degree useful as a means of affording light. And in Sir H. Davy's own pamphlet on flame, &c., page 15, it will be found that Sir H. Davy was not so ill informed on this subject as has been represented. Sir H. Davy there says, "Some phenomena that I observed in the combustion of a blower, induced me to believe that small quantities of olefiant gas might sometimes be evolved in coal-mines with the carburetted hydrogen; I therefore resolved to make all lamps safe to the test of gas produced by the distillation of coal." Sir H. Davy even goes further on this most important point. At page 144 of the same pamphlet, Sir H. Davy says, "If pure hydrogen should be disengaged in any mines, the improbability of which is, however, very great, wire of a finer texture must be employed." Dr. C. says that while in town he made a promise to Mr. Pease and to Mr. Nicholas Wood, who is described by him as not only "an experienced," but as an "accomplished viewer," to analyse some of the most explosive fire-damp of coal-mines in

this district, which it appears the Doctor has done. Now with reference to his analysis of fire-damp, I beg to remark that from his statement, it might be inferred, that this gas is naturally less inflammable than coal-gas. That it generally appears so when analyzed is true, but to believe that it is always so, is an error, which has no doubt been productive of many of those lamentable accidents that have of late been so frequent and so severely felt in some of the mining districts; and which error therefore cannot be too speedily corrected. Fire-damp in its pure state is called "light carburetted hydrogen," from its having less carbon to its bulk of hydrogen than the common coal-gas. Consequently when in its pure state, mixed with a proper proportion of atmospheric air, it approaches, in inflammability, perhaps nearly to hydrogen itself and atmospheric air. Happily for the miner, it is very seldom found in this pure state, and never perhaps can be so, unless suddenly evolved in large quantities. Sir H. Davy states, pp. 30, 31,—“I mixed azote and carbonic acid in different quantities with explosive mixtures of fire-damp, and I found that, even in very small proportions, they diminished the velocity of its inflammability. Azote in the proportion of one to six of an explosive mixture containing twelve of air and one of fire-damp, deprived it of its power of exploding; and one part of carbonic acid to seven of an explosive mixture, also deprived it of the power of exploding; so that its effects are more remarkable than those of azote.” Several other eminent men have shown that it is scarcely possible to get two specimens of fire-damp of the same quality. The variations of the quantities of its admixtures, which most always depend materially on local circumstances, it appears sometimes extend to at least 50 per cent. The experimentalist on a small scale is therefore frequently deceived, for he can scarcely ever come a second time to the same conclusion. Indeed he seldom gets it tolerably pure, as it is generally taken within the natural reach of the person employed, where it cannot be otherwise than greatly contaminated with carbonic acid and nitrogen. I can, from my own experience, speak of a great difference in the inflammability of two specimens of this gas. The fire-damp which was taken at a height of about twenty-five feet from a sumpt, was so highly inflammable, that its flame readily passed through a Davy lamp; while some taken near the floor of the same mine, at the base of this sumpt, had no material power on the lamp, and perhaps would not have been dangerous with a naked light. These facts show how carefully experiments, or opinions on the subject should be scrutinized. The fire-damp may come in any coal-mine, as it did so lately at the Wallend Colliery, in a state no doubt far more explosive than it

had been there for the preceding twelve years. But it came, and suddenly swept all away. No man therefore can be expected to be attended to who recommends that any extent of security which can be obtained, should be dispensed with where the smallest want of that which is quite sufficient, is generally attended with destruction.

I shall close my letter, which I now do, that I may not overreach too far, if I have not done so already, on your valuable space, without taking notice of the allusion made by Dr. Clanny to the parties “concerned in uprearing a well-puffed safety-lamp;” nor to his intended insulting reference to “a pitman,” “a lamp manufacturer,” or other insinuations which may be considered as personally offensive, and remain, Sir, your obedient servant,

GEORGE UPTON.

64, Queen-street, Cheap-side.

22nd Sept., 1835.

[We have taken the liberty of suppressing from this letter every paragraph which would lead to useless and valueless controversy.—Ed. L.]

THE LANCET.

London, Saturday, October 10, 1835.

THE very persons who possess less than the least influence in the election of medical officers in our public charities, are of all persons the most likely to be injured by a bad choice of hospital functionaries, and the most certain to be benefited by a good one. Those persons are the patients. The position which they occupy as claimants for the bounty of the charity prevents their admittance to the suffrage, excepting by a mode which must be described on another occasion. Every man, however, of a liberal and benevolent mind,—all those, in fact, who would place elections to public medical offices on a foundation which will ensure to the sick poor, efficient remedial aid, admit in theory the propriety of granting an influential voice in the choice of medical attendants to the inmates of our national hospitals, for in the hands of those attendants are often placed the awful destinies of life or death.

but since the direct concession of the suffrage to the hospital patient is not in practice, the duty falls on those who hold the reins of government in our medical authorities, to substitute for the corrective force of the most deeply-interested parties, the system of appointment which fully disguises in the object of the election the gross benefit of the afflicted inmates, and tends to render subservient to that end every other consideration.

Unquestionably the form of appointment should be such as will test the talents and scientific acquirements of the various candidates, and admit of a fair comparison between the degrees of merit displayed, and provide the means for competent arbiters to pronounce a just decision as the result of that comparison.

The truth of affirmative positions often must be established by the evidence of negatives, which, unhappily, are too often within the reach of those who would abolish abuses in government, and erect in their place sound principles of legislation. Inevitably does it happen, for instance, in medical arrangements, that the advantages of a sound code of laws must be enforced by exhibiting the deformities of one which is imperfect and corrupt. On such a pre-emptory are we thrown in the pursuit of an object which at present occupies our attention. We shall first hypothesize a case, and then prove its reality.

Suppose that the election of a surgeon to an Infirmary is about to take place in one of our county towns, and that a large body of persons has assembled before the tribunal of judgment to witness the proceedings and to assure themselves that the duty which the governors of the institution owe to the poor and sick amongst their brethren in the community, whom they invite to enter its walls, is strictly, conscientiously, and directly fulfilled.

The first speaker rises to take his share in the proceedings, and makes known to his auditors the peculiar grounds on which he claims admission to the

arena of competition. "All men would expect that the grounds of these claims should alone occupy his mind; because the right of admission as a candidate at all, requires first to be established; for a lawyer should not compete for the vacant office, nor should a soldier, nor a merchant, nor an artisan, nor, in order to prevent a waste of time, without impeding the principle of proceeding, should a known tyro in surgery. Amazement, however, surely would affect the assembly, on finding that the very proofs of the right to compete were converted at once into "reasons" for forthwith electing one particular man to the office, in preference to every other candidate. Great, surely, would seem the dereliction from a just principle, of that functionary in the election who should forthwith fill his exhortation to the electors with "reasons" based on unprofessional experience in affairs of medical science, and immediately pronounce a decision in favour of a yet untested candidate. Say that for decency the speaker prefaces his observations by an admission of the high importance of the duties to be executed,—of the great "responsibility" which will attach to the chosen officer, and of the necessity that, for the welfare and "comfort of the unfortunate patients," none but "professional grounds" should influence the decision of the meeting. Then thus imagine him to proceed, plunging at once in *medias res*:—"Friends and electors! I commend to your choice Mr. Surgeon DICKIN. First; because he has written a *very modest, delicate, and humble letter of solicitation to the trustees*. Therefore you ought to elect him to cure the patients in this hospital. "Secondly: because private inquiries into his education and character convince me that he possesses very high *natural abilities*, that he has received the *very best education in the first schools of Europe*, bringing his education and abilities to bear on his professional pursuits in such a manner as eminently to fit him to cure the patients in this hospital. "Thirdly: His teacher and partner in medi-

"cal practice, recommends in the strongest manner that he should be elected surgeon to the institution; therefore you ought to elect him. Fourthly, because six summers back he ceased to be a student, and comes before us therefore now with years of venerable experience on his head. Fifthly: because, since he received a license to practise, he has possessed the very best opportunities of daily witnessing the newest discoveries (numerous as drops of hail in winter) in surgical treatment; while the other candidates have been kept in ignorance of these discoveries, by constant employment in their libraries at home, and in the sick rooms of patients in long-established practices in this country town. Sixthly, my friends, and above all,—weightier in the scale of his professional qualifications even than the recommendation of his partner,—is the fact that he has passed many years (as a pupil) in this very infirmary, seeing daily its practice, and getting intimately acquainted with the habits and peculiarities of its usual inmates. Seventhly and lastly: The medical officers of the establishment, though none of them personally interested in the election of their juvenile half-colleague, have declared that he ought to be elected. It matters not that the inmates, whose habits and peculiarities he has studied, were patients in the infirmary several years since. Habits and peculiarities run in the breed of Salopian hospital inmates, and will be the same in those of 1836 as they were in the inmates of 1829. Mr. DICKIN therefore you should elect. Moreover, none of the other candidates have obtained the recommendation of the medical officers of the infirmary. On the contrary, it is a very general custom for the physicians and surgeons in country hospitals and infirmaries, to prevent their brother practitioners from possessing the opportunity of witnessing the practice of those institutions; and of course they could not recommend gentlemen whom they purposely avoid in the hospital.

"Gentlemen, these facts are overwhelmingly influential with me, and I feel honoured in proposing Mr. DICKIN to you as a surgeon to the patients in this infirmary."

Probably a clergyman, an equally excellent judge of the professional claims of a surgeon, seconds the nomination.

Who would not laugh at this proceeding as at a scene in a farce,—or start at it as a mockery of the claims of the patients, and a grossly unjust attempt to influence the electoral judges against the claims of able and experienced men who had not written "delicate" and "humble" letters to the "trustees," though possessed of "high natural abilities," and educated in the first European schools,—who possessed no certificates from "partners," nor the privilege of admittance to the practice of an hospital where the oracular authority of the "newest discoveries in surgical treatment" was a youth of five or six and twenty,—and who had only been employed daily for twelve or twenty years in treating disease amongst individuals whose "habits and peculiarities" were not characteristic of a particular set of sick patients?

Yet from the life have we made this sketch, and such another could we draw from the life in every number of our journal throughout the year.

Let the reader judge how faithful is the illustration, and reflect on the facts which it exhibits, by perusing the following extract from the *Shrewsbury Chronicle* of the 25th ultimo. Well may the sounds of "cheering" and "continued cheering" which attended the exordium of Mr. GORR, have been arrested at the point of their actual cessation. Most appropriate were those demonstrations as indicated by the reporter, but for the assembly presently to withhold them, became a duty which was well observed. The sentences are transferred *verbatim* to our columns:—

"Election of a Surgeon to the Infirmary."

"The trustees of this institution, to the number of upwards of 300, assembled in the Infirmary, on Friday last, to elect a surgeon."

in the room of Mr. Humphreys, resigned. There were as candidates, Messrs. Higgins, Clarke, Dickin, and W. J. Clement; but the first-named gentleman resigned, and the second did not proceed to a poll; the contest, therefore, lay between Messrs. Clement and Dickin.

"W. O. GORE, Esq., M.P., rose and spoke, —It has fallen to my lot, my Lords and Gentlemen, to nominate Mr. Dickin as surgeon to this very useful institution; but before doing so, I will briefly state the reasons that have induced me. Some time ago Mr. Dickin applied to me for my support at the election, and that I should propose him. I declined; because, although I knew his connexions to be highly respectable, still I knew not enough of Mr. Dickin professionally to support his pretensions to occupy a situation of such responsibility; for I think that this election is to be decided on professional grounds alone, and not on any personal, far less political ground (*great cheering*), but solely with an eye to the character of the institution, and the comfort of its unfortunate inmates. (*Continued cheering*.) When, however, I read the very modest letter which he addressed to the trustees, in which he claimed nothing, but stated his pretensions with equal delicacy, modesty, and humility, I could not resist making further inquiries into his education and character; and these inquiries satisfied me that Mr. Dickin was a gentleman possessing very high natural abilities, having received the very best education in the first schools in Europe, and brought that education and those abilities to bear on his professional pursuits in such a manner as to gain him the approbation of all around him, and eminently to fit him for the situation to which he now aspires. From his tutor, and partner, Mr. Humphreys, I received a letter, recommending Mr. Dickin in the strongest manner; and as no man could possess better opportunities of knowing him, I could no longer hesitate in affording him my humble support. The testimonials which Mr. Dickin has this day laid before you, are such as few young men ever produced. Few men of his standing have seen so much hospital practice, a species of knowledge so valuable in this institution. In 1829 he received his diploma, and since that period he has been studying in Edinburgh, where he has had the very best opportunities of daily witnessing the newest discoveries in surgical treatment; whilst the other candidates have been precluded from this advantage, by their other professional labours. But above all, he has passed many years in this very house, seeing daily its practice, and getting intimately acquainted with the habits and peculiarities of its inmates; and so zealously did he perform his arduous duties here—so diligent and attentive was he—that he gained the confidence of every patient that was

received within its walls, but of every medical officer upon the establishment, who have unanimously joined in recommending him as well fitted for the situation. Such recommendation is of the highest value in enabling you to come to a satisfactory decision. None of the other candidates comes before you so recommended; and no such names as Darwin, Du Gard, or Johnson, would be attached to a document, were these honourable men not aware that the person they recommended was worthy of the praise they bestowed. I therefore feel honoured in proposing Mr. Dickin to be elected as surgeon to the Infirmary.

"The Rev. Mr. COTTON seconded the nomination."

We have thrown the burden of exposing these absurd grounds of recommendation on the fictitious oration of one of the judges in this concours of friends, and, as we hear, political partisans. But the speech in which the claims of the second candidate were urged, may obtain from us a more pointed exposure of the errors into which the system of election upon simple nomination is calculated to lead the self-appointed guardians of the public health. When Mr. GORE had concluded,

"Archdeacon BUTLER rose and said,—My Lords and Gentlemen, I come forward in behalf of one who was for some time my pupil; who then conducted himself much to my satisfaction, and gave the promise of those talents which his after life has so amply redeemed. But he has a stronger claim to my services than this, arising from the many and great obligations which I feel myself under to his father and himself, for the skill and attention which they have shown for many years in their professional capacity, while attending two-thirds of my family. I have seen the medical skill of the latter exercised with a happy combination of promptitude and judgment, on more than one critical occasion,—where the result has been eminently successful,—where delay would have been ruinous, and where but for such decision the issue must have been fatal. (*Cheers.*) Mr. Clement's testimonials are before you, and when among the host of first-rate practitioners you find the names of that great anatomist and surgeon Sir Charles Bell in the surgical, and of Dr. Southey, physician to his Majesty, in the medical department, and consider the terms in which they have spoken of him, I may call them not merely respectable or unexceptionable, but of the highest order; and I am sure you will acknowledge that I am not using too strong a term to describe them. But he has something still stronger than

these to produce. I mean the direct evidence of his own talents—his own experience—his own *extensive practice*—his own operative skill—all of which are not only before the eyes of his professional contemporaries in this town and neighbourhood, many of whom, in so unusually kind a manner, have come forward to attest them, but of the whole medical world. Mr. CLEMENT has given proofs of this in his Prize Essay, for which he obtained the Pothergillian gold medal in a competition open, I believe, to all Europe; and in the volume which he has published, which has been translated into other languages, and of which, though I am not competent to speak professionally, I can trust the opinions of those who are, many of which you will find annexed to his printed testimonials. From these you may learn the ardour with which he embraces his profession, and the skill with which he conducts it; the fair reward of which, I trust, he is about to reap this day at your hands. And with this hope, my Lords and Gentlemen, I shall beg leave to propose Mr. William CLEMENT, as a fit and able candidate to fill the office of surgeon to this Infirmary. (Cheers.)

That of these two candidates Mr. CLEMENT was, on the ground of experience, the fittest man to fill the vacant office, we have no doubt. That either of the candidates was not an accomplished surgeon, we have no reason for believing; certainly, however, the probability of efficiency was in favour of Mr. CLEMENT. Yet Mr. CLEMENT did not obtain the appointment, and two other gentlemen were expressly driven from the field of competition by the mode of election,—by the institution of the false basis on which the points of merit were made to rest. But how could Mr. CLEMENT, or any candidate, expect to be elected, who suffered his claims to consist of the following grounds of recommendation? First, the voucher of his schoolmaster, that he was a clever boy. Secondly, the declaration of a private patient that he was under great obligations to the father of the candidate and the candidate himself, for the exercise of their professional skill and attention. Where is the patient in private life, who would not say the same of the medical attendant of his choice? Lord INGESTRIE and Sir FRANCIS BURDETT bore a precisely similar testimony to the skill and attention of JOHN

LONG, and everybody laughed at them as a couple of dupes. Why, the first examiner of medical talent in the world could not, with all his fitness for the office, have pronounced a higher eulogium on the medical "skill" and "judgment" of a candidate for office, than fell from the lips of the arch-deacon. Thirdly, Dr. BUTLER urged the "unexceptionable" weight of the written "testimonials" of Mr. CLEMENT. Testimonials! Why, the very name stinks in the profession. The testimonials of teachers and private friends! Hardly a name of reproach is there that can be attached to scriptorial impositions, which has not been publicly given to them by this very class of testifiers themselves (when hard pressed), as every reader of the evidence taken before the Parliamentary Medical Committee well knows. Fourthly, the electors are referred to the fact that Mr. CLEMENT is occupied in a most extensive private practice, his skill in which is notorious to his professional brethren. To say nothing of the singularity of urging the election of a gentleman who is already well occupied in a "most extensive" practice, to an office in a large county infirmary, let us observe that the skill and science of a private practitioner can be but indifferently observed by his professional brethren, and are liable to present too many deceptions to justify reliance upon them from hearsay or general belief. Moreover, the "professional contemporaries" who were declared by Mr. GORE to be the best judges of the skill and judgment of a Salopian surgeon, actually gave their decision in favour of another candidate. But the error of trusting to written and verbal grounds of recommendation in medical elections is made more palpable, if possible, by the addition of the claim set up by Dr. BUTLER, relative to the competition of his pupil for a medal, which, although nine-tenths of the professional world probably never thought twice of its existence, yet said to be open to the struggle of "all rope." The climax of these recommendations, however, is contained in the

that the appointment may be given as a "reward" for,—ah, a reward for what? Truly, puzzled are we to say. Most probably no salary sweetens the labours of the office in the Infirmary, and the just execution of its duties must actually deprive Mr. CLEMENT of part of the very income which he derives from a highly remunerative circle of private patients. A reward, then, for what, and what kind of reward would the possession of this appointment be to Mr. CLEMENT? Archdeacon BUTLER begs the trustees to double the labours of a gentleman, as a recompense for that portion of them for which he has actually already been paid! What a very funny mode of proceeding! How odd a system of reward! Had the trustees liberally attached a salary of three or four hundred pounds a-year to the office of chief resident surgeon, and then opened the post to public concours, the word "reward" might not sound so very foreign to the occasion. It might with a good grace attend the annual presentation of a check for the salary; but as matters at present stand, we certainly do not comprehend the term. We know what is meant by the "benefit" of the *patients*. We wish that that was better understood. Alas! it is the very weakest spring of action in English hospital elections. Yet, *professedly*, it is the be-all and the end-all of public medical charities. A third speech was made at the Salopian Infirmary, and in that speech was large talk of the *patients*. No feelings more considerate, indeed, could have influenced the orator than were expressed in the introductory passages.

"I rise," said Mr. BATHER, "to second the nomination of Mr. Clement. Mr. Gore has told you that neither *favour* nor *affection*, neither *political partiality* nor *personal predilection*, should bias our votes on this occasion; and I, on behalf of Mr. Clement, most cordially subscribe to the doctrine. (*Cheers.*) Most heartily do I trust that the advice thus given will be acted upon thoroughly in our quiet selection. (*Cheers.*) Perhaps, on *such* occasions as these, the best feelings of our nature are the most likely to mislead us. Even *gratitude*, the most exalted feeling of

ments and our desire, and lead us to forget the former while seeking the accomplishment of the latter. And when that gratitude is called forth by sufferings alleviated,—or *affliction* soothed,—or death averted,—or health and enjoyment being restored into the place of misery and suffering, in our own persons, how easily may we be led to forget our duty, and to remember only our gratitude! (*Cheers.*)"

This is eloquent and true, but how was the well-cheered theory observed in practice? Let the recommendations urged by Mr. GORE and Dr. BATHER furnish answers to the questions. To these Mr. BATHER added another claim, but such another as every practitioner in Britain could supply for himself by the dozen. He said,

"In this case, with all the strongest ties of gratitude wound close around us, we are freed from any terror of being misled by such feelings, in the perfect knowledge that the skill which averted our sufferings is, if you will permit it, to be employed in alleviating the affliction of the humblest of our fellow creatures;—that the decision which averted from us the pangs of death, is proffered openly to all; and that not by the wealthy alone, are zeal and promptitude, and skill, and talent, to be obtained, but by the poorest and most destitute those qualities may be commanded, if you will this day permit them to be accepted. (*Cheers.*) Dr. Butler has told you that to Mr. Clement and his father is entrusted the health of two thirds of a family, not exceeded in number or respectability, you will allow, by any in the kingdom—certainly not exceeded in any case in the care which is bestowed upon them by that gentleman's family. My reverend friend has also told you that in the humanity, promptitude, and decision of Mr. Clement he had the utmost confidence, and to those qualities he attributed much of the healthful enjoyment of his pupils: he has further drawn such a picture of what might have arisen from the want of those qualities, from less care, less promptitude, less zeal, or less decision, as must deeply have impressed your minds with their value. Gentlemen, if Dr. Butler so feelingly speaks of Mr. Clement's abilities as regards his pupils, with what depth of feeling must I speak of him, when to the successful exertion of those qualities, under God, I owe the life of my own son; for to that zeal, promptitude, and skill I owe his preservation! (*Much cheering.*) Surely, then, if gratitude forces me to what my cool judgment would otherwise lead me, I cannot be far astray in following their dictates. (*Cheers.*)"

It was sad to see the gashes which Mr.

BATHER, as the advocate of Mr. CLEMENT under the imperfect system, kept inflicting on his own throat. He could see the mote in Mr. DICKIN's eye; the beam in Mr. CLEMENT's, obstructed his vision.

"This," said Mr. BATHER, "is essentially a case to be decided by your opinion of the comparative superiority of one candidate over another. You are bound to select the best, or you betray your trust. We can speak well of each candidate. But look at the evidence. The first class consists of proofs of those steps which enable the candidates to offer themselves as qualified to fill the situation. But we cannot permit Mr. Gore to hold forth that as a recommendation which is only a certificate. We cannot allow him to say that Dr. Darwin has recommended him in preference to the other candidates, when he has only certified that he properly attended his duties in his situation: and which certificate could equally be obtained by any young man who properly conducted himself. (Hear, hear.) Mr. Dickin's testimonials are all to a similar effect. Great hope have the writers that he will prove in time a useful surgeon. (Laughter.) We show you the eminence Mr. Clement has already attained. Can you hesitate which you should select, if you mean honestly to benefit the patients in this infirmary? The abilities of the candidates are to guide you in that decision. (Cheers.) Yet Mr. Humphrey's recommendation must be taken with all due allowance. Mr. Dickin has been his pupil; he has now become his partner, and to him therefore the partialities of its chief will naturally incline. For see how these matters are conducted. Mr. Sandford was the original founder of the firm; he in course of time retired, and handed over the business to Mr. Humphreys, with the surgery to this institution attached; and now that Mr. Humphreys is about to retire, Mr. Dickin is to succeed him, and the surgery follows as a matter of course, being handed over from partner to partner, like the scalpel and the gallipot. (Cheers and laughter.) Poverty and disease are surely sufficient afflictions; let us not add to them other evils of a yet more horrid sort; let us not promise them relief, and give them disappointment. (Cheers.) If you were to throw overboard all Mr. Dickin's testimonials, the same number abstracted from Mr. Clement's would not be missed: for his experience and repute would remain; and on what other grounds can you choose an operating surgeon? What say his fellow surgeons of him? Has he not produced a list of the most eminent surgeons in the county, strongly recommending him to your choice, throwing aside all professional jealousy, and they are but a jealous and waspish generation. Mr. Clement has given to the world his "Observations in Surgery,"

which all persons qualified to give an opinion have highly lauded. The French and Germans have translated it. Can higher testimonials be borne than the united praises of the three greatest nations in Europe? I conjure you to reflect on the condition of those for whom you are acting. I ask you, not for Mr. Clement's sake, but for the sake of the Infirmary, to appoint the man whose experience and abilities best qualify him for this place."

"Not for the sake of Mr. Clement?"—Why, what said Dr. BUTLER, the coadjutor of Mr. BATHER? Dr. BUTLER expressly demanded the appointment for the sake of Mr. CLEMENT,—for his "reward,"—as the Doctor phrased it. And these incongruous sentiments fall from the lips of two of the most prominent and influential conductors of the election! Is there no gentleman within the sound of Shrewsbury clock who will take the trouble to explain to these worthy and most respectable gentlemen,—and such they are in every sense of the words,—the conduct, object, efficiency, and security of the concours? Conviction on those points might do some good at the next vacancy.

The meeting was evidently in favour of Mr. CLEMENT, but part of the judges were non-residents, or at any rate non-presents, for—

"Immediately on the conclusion of Mr. Bather's speech, a show of hands was called for, which was considerably in favour of Mr. Clement. A ballot was then demanded, in order to introduce the proxies, when the numbers were announced—

For Mr. Dickin	221
For Mr. Clement	168

"A vote of thanks was then moved to the Chairman by Mr. Bather, seconded by Mr. Sheppard; and the meeting dispersed."

We shall pursue the matter only a step farther at present. We cannot before leave it refrain from asking how it happened that Mr. CLEMENT, a gentleman who had, probably, no need to fear the contest, said not one word throughout the period of canvass about the election by concours? In that form of appointment how would the weak and unworthy have gone to the wall! With what tenfold honour

ful competitor have entered on the duties of the office! How manifest then would have been to the trustees and the public the propriety of remunerating the great skill and talent which circumstances had rendered prominent! We do not for a moment believe that Mr. DICKIN would have avoided this test of his qualifications; and what an example would he have set, what fame might he have acquired, by insisting that it should be instituted! That *he*, at least, could have carried the point, who can doubt? If 221 friends would vote for his appointment under an absolutely worthless system of "trial," how much more readily, urged by his demands, and fortified by his confidence,—would the majority of the trustees have made an arrangement for a public and an honourable concours between him and Mr. CLEMENT! He has missed a point which he may never retrieve. We hope the patients in the Infirmary will have no cause to regret the want of courage in the candidates (if *that* were the want) which led the trustees into the gross error they committed in tolerating another election under the old, inadequate, and corrupt system of election.

WE this week afford our readers three or four specimens of the kind of matter which occupied the attention of the medical students in the metropolis this session at the introductory lectures. *Jam satis*. The system is by this hour of the month in full swing. It will die at not one point of advance beyond its merits at the day of its birth.

We observe that Sir C. BELL ascribes the rise of the Middlesex Hospital School to a desire to reobtain the pupils who have been drawn from that hospital to the hospital of the London University. What a mistake *just* remedy! The governors should have thoroughly amended the *Middlesex Hospital* as a school of instruction, and then no pupils would have left its walls. Do they not

see that it is the *North-London Hospital* which attracts students to the University lectures? How wayward in their principles of legislation are the old folks in the hospitals!

Sir CHARLES BELL referred in his address to his Parliamentary Evidence. He is one of the few men of his class who can afford to do so. His opinions on medical legislation, for the most part do his courage and his discrimination credit. Let those medical students who have not yet perused them, learn what a man who has deservedly risen to the highest pinnacle of professional fame in this country, solely by the aid of his own industry, thinks of the present system of medical education and practice in England. They will find his evidence recorded in *THE LANCET* of the 25th of July last, No. 621. And while referring to it, we may take the opportunity of adding, by way of postscript to our recent remarks on the study of anatomy, and on the fraudulent system of lecturing students into a knowledge of medicine, the following remarks of Sir CHARLES on those subjects:—

"When a young man retires from his studies, and is solely dependent on himself in practice, the knowledge which he feels the greatest difficulty in supplying, is that of anatomy. In speaking on the subject of education, I wish to distinguish between lectures which require demonstration, and those which are *mere discourses*. Anatomy and chemistry require demonstration. *These*, therefore, are the most essential to be taught by lecture. The practice of medicine and surgery requires to be taught by *the bed-side*. Elementary courses on these subjects may be supplied by diligent *reading*. To crowd a curriculum of medical study with a variety of courses, would be little conducive to a good end. There is a disposition to diminish the importance of anatomy. Yet anatomy is the groundwork of all. From that science, not only the elements but the great rules of the profession are to be drawn. I do not think that there has been any advantage derived from *multiplying professorships, and dividing and subdividing the subjects of lectures* (into so many courses). I fear it has often been done *for the purpose of providing for individuals*.

EMMENAGOGUE PROPERTIES OF ACONITUM.

In a paper by M. WEST of Strashtorg, in the August Number of the *Archives Generales de Med.*, M. WEST states that aconitum is one of those remedies which after having been praised beyond all measure, like many other new remedies, is now completely neglected in France. In Germany a few physicians still employ it in some cases, particularly in phthisis and rheumatismal affections. The author, while attending the clinique of the School of Medicine at Vienna, has seen a great number of experiments with this remedy. In phthisis its action never appeared very advantageous, but always inferior to that of the other narcotic substances. Its utility in cases of rheumatism seems more doubtful. However, amongst other patients at the school of Vienna, the author observed two females on whom the action of aconitum was very remarkable. One was a stout female, 27 years of age, affected with articular rheumatism of the left arm: her menses had been suppressed for three months in consequence of exposure to cold. Aconitum joined to antimony was administered for the rheumatic affection. The latter persisted without any change, but the menstrual discharge was quickly restored.

The second case was that of a female, 32 years of age, equally affected with rheumatism, whose catamenia had not appeared for five months: she took aconitum; the pains diminished slightly, and the menstruation was restored. These cases roused the author's attention, and induced him to make further experiments. He details three examples of successful application of the remedy to amenorrhœa. In the first, the disease had been established for twenty-two months: the patient was bled, and took the watery extract of aconitum for eight days previous to the supposed menstrual period. On the 5th day the pupils appeared dilated, with other slight indisposition: on the 8th day the menses reappeared, and have continued regular since that period.

In the second case, that of a weakly girl, the menses had been suppressed four and a half years, and replaced by a leucorrhœal discharge, more abundant at each period. The patient took thirty grains of the extract

in twelve days, for suppression of the leucorrhœa, accompanied by pain and weight in the summit of the vagina: on the 10th day the pain had much diminished, and the white discharge had returned.

In the third case, the girl, 19 years of age, began to menstruate at the age of 16; ~~after~~ the lapse of a year the discharge was suddenly arrested in consequence of exposure to cold. After five months the patient experienced severe pain in the head and abdomen. These soon changed into true hysteria, the access of which came on at each menstrual period, and was excited by any moral emotion. The patient was seen a year after the suppression of her catamenia, and then exhibited the symptoms of chlorosis in the highest degree. She was ordered general and local baths, with thirty pills of the extract, to be taken eight days before the expected period. After the use of twenty grains the catamenia appeared, and were succeeded by a very fecund white discharge; from this moment the access of hysteria disappeared, and the patient gradually recovered her health.

From these facts and several others noticed by the German writers, the author thinks the efficacy of aconitum in cases of amenorrhœa cannot be doubted; as to its mode of action, the author thinks it may determine the reappearance of the menses, not by any specific property (for there does not exist any absolute emmenagogue), but by calming an irritation of the uterus, by which the vessels furnishing the menstrual flux are prevented from performing their ordinary function.

RE-VACCINATIONS IN THE ARMY OF THE WURTEMBERGIAN STATES IN 1833.

Professor Heim states in the *Wurtemb. Mediz. Correspond.*, Nos. 10 and 11, that 1683 individuals were re-vaccinated with the following results:—34 in each 100 with success; 22 with modified results; 44 without any result. The patients were from twenty to thirty years of age. Of 577 who were re-vaccinated with perfectly successful results, 293 showed good cicatrices, 116 imperfect, and 168 presented no cicatrices at all. Of 366 re-vaccinated with imperfect results, 193 had good marks, 134 imperfect, and 39 no cicatrix at all. Finally, of 740 persons re-vaccinated without any result, 382 showed good, 222 imperfect, and 136 no cicatrices.

THE ARTERIES IN INFLAMMATION.

To the Editor of THE LANCET.

SIR,—In the last number of the *Medical-Chirurgical Review* there is a notice of Professor Alison's paper on the vital properties of arteries, &c. I was glad to find, on a first perusal, evidence, as I thought, that the journal had changed its opinion regarding the state of the vessels in an inflamed part, and of those leading to the part. On re-reading the article, however, I was surprised to find that there was no change in opinion, but that the doctrine advocated by the Professor had *always* been considered by that journal as the true doctrine. In my own mind, from what I had gleaned from the pages of the *Medical-Chirurgical Review*, I had settled that it was opposed to the doctrine of *debility* of the vessels in inflamed parts; and I was sorry for it, because from its high repute and great circulation it became a powerful means of extending an error which has occasioned immeasurable mischief. Afraid that I had all along laboured under a misconception of the sentiments of the journal, I have referred to former expressions of these sentiments, and will briefly transcribe from its pages some of the remarks on which rested my opinion of its creed.

At page 498 *Med. Chir. Review* you will find the following passage:—"Every one knew that vessels leading to inflamed parts were dilated; and it is nearly half a century ago that numerous experiments were made in Edinburgh (Lubbock, Allan, Wilson), to prove that the capillaries were *weakened* and dilated in inflammation, and consequently that the circulation was *actually slower* in inflamed than in sound parts. We have *always* considered this as the true doctrine of inflammation, and we are glad to see so able an advocate of the same in the person of Professor Alison."

Compare with the above the following, which you will find at page 411, *Med. Chir. Review*, October 1832:—"The prevailing opinion at present appears to be that the capillary vessels are *weakened* and dilated, because by reason of that weakness, they are unable to resist the *ordinary* force of the heart and large vessels. This has *always* appeared to us a fallacious theory, although we are willing to allow that it is a specious one."

Of course the journal could not but admit of a dilated state of the vessels, but I am not aware that it ever until now admitted, that the vessels in acute inflammation were in a *weakened* or *debilitated* condition; on the contrary, it has laboured to upset the doctrine. "The treatment, then, of inflammation," the reviewer says, "should teach us something of its nature. It tells us this,

that inflammation is not always the same, that acute inflammation is remedied by what empties and relaxes the large vessels and the small, that certain forms of chronic inflammation are best treated by what astringes and gives tone to them. Who does not know that phlegmonous inflammation is best treated by depletion, local or general, or both; and by the application of warmth and moisture, agents especially calculated to relax? We think this instance sufficient to upset the doctrine which makes inflammation consist in *debility* of vessels."—*Med. Chir. Rev.*, October 1832, p. 414.

Is there not a change of opinion also as respects the velocity of the circulation in the inflamed part? We now learn from the journal that it has always considered this as the true doctrine of inflammation, viz., weakened and dilated capillaries, consequently circulation *actually slower* in inflamed than in sound parts. Witness how the reviewer expresses himself in October 1832, p. 412. "An inflamed part, if formerly white, becomes more or less red, and, if previously red, it is rendered redder. This arises, of course, from the greater quantity of blood which is in it. But we must not stop here, venous blood and arterial differ in colour, and, for precisely the same reason, blood circulating slowly is less florid than blood circulating rapidly. In phlegmonous inflammation the colour is vivid, not only because there is much arterial blood in the part, but also because that arterial blood is frequently renewed; in other words, because it is circulated with *rapidity*." I remain, Sir, authenticating my communication privately, your obedient servant, O. B.

EASTERN MEDICAL ASSOCIATION.

To the Editor of THE LANCET.

SIR,—May I request that you will do me the favour to insert in your next *LANCET* a correction of an erroneous reference to myself in the report of the "Formation of an Eastern Provincial Medical Association" (condensed from the *Bury Herald*). In Mr. Bedingfield's speech I am called Dr. Rumsey, and am said to be president of the Bucks Medical Association. I disclaim, however, both these honours, being only a general practitioner, and holding no office in the Bucks Medical Association, of which, nevertheless, I am a member and a sincere well-wisher.

The mistake doubtless arose from my having mentioned to Mr. Bedingfield that I am secretary to a committee appointed by the Provincial Medical and Surgical Association, held at Oxford in July last, for inquiry into the present state of parochial medical attendance, &c. &c. In this capa-

city I shall be happy to receive all the information which my medical brethren in the country can afford me; and I take this opportunity of gladly thanking you for the zeal with which you have, both in your editorial and parliamentary capacity, advocated the cause of the country practitioners, in their opposition to the disgraceful proceedings of the Poor-Law Commissioners. I have the honour to be, Sir, your obedient servant,

H. W. RUMSEY.

Chesham, Bucks, Oct. 5, 1835.

REFUSAL TO OPEN A BODY AT AN INQUEST,
WITHOUT REMUNERATION. — VERDICT
WITHOUT EVIDENCE.

To the Editor of THE LANCET.

SIR,—I beg to transmit to you some particulars of a coroner's inquest which lately took place in this neighbourhood, and to which I was summoned as the medical witness. I do so for the purpose of enabling you to decide whether my conduct was *legal* or not in refusing to open the body without possession of a written order from the coroner. If I had opened the body without such order, could I have successfully supported a demand for remuneration in a court of law; and against whom? You would greatly oblige me by answering these questions, as I have to make my appearance at the Old Bailey on the trial of the husband of the deceased. The subject of remuneration to medical men at inquests, being now of peculiar interest to the profession, you are at liberty to insert the following in the next number of your valuable Journal.

A woman named Sarah Goodlad came to the Western General Dispensary on the 13th ult. with an injury which she said she had received from falling on a pail. I examined her side (the part affected), and believed there was a fracture of one or two ribs. I treated her accordingly. Inflammation of the lungs came on in two or three days afterwards, and in spite of the most active treatment she died on the 19th ult. An inquest was held on the body, as it had been reported that her husband had beaten her (indeed she stated to a neighbour that her husband had been the cause of the injury). This came out in evidence before the jury, and it was stated that he had thrown a loaf of bread at her. It seemed to me from this that there was sufficient evidence of injury inflicted by the husband to account for the fracture, but most of the jury did not think so. They had heard evidence respecting some slight accident which happened about a month before I saw her, and it would seem from their verdict, that they partly believed

the previous injury to have been the cause of the fracture. Three of the jurymen, however, were not quite convinced on this point, and I was asked if a post-mortem examination would make the matter any clearer. I said most undoubtedly it would. The coroner (Mr. Stirling) therefore asked me to open the body, which I told him I would immediately do if he would give me a written order by means of which I should obtain remuneration for the trouble. This he refused to do, saying that he never had done such a thing. His clerk (who really was the chief man on this occasion) then told the jury that there would be no difficulty about the matter, though I had refused to open the body, for he would write to a vestryman of the parish who would send one of the house-surgeons from the parish infirmary to do it.

The inquest was accordingly adjourned to the next day at three o'clock, when the jury met, and waited for some time for the evidence of the medical men who was to have opened the body; but it appeared on inquiry that the body had not even then been opened; neither did either of the infirmary medical officers attend the inquest. The patience of the jury being now exhausted, they made up their minds to deliver the following singular verdict, *the body not having been opened*: "Died of inflammation of the lungs, brought on by fractured ribs, but by what means the fracture was occasioned there is not sufficient evidence to prove!"

Now, Sir, if the public will allow verdicts to be passed in such a manner as this, they deserve to suffer from the consequences. It certainly was not a just request to require a professional man, whose time and knowledge were his property, and whose reputation as a witness was at stake, to make a post-mortem examination, without the least remuneration, and perhaps with insult. My motive for refusing on this occasion to open the body, arose chiefly from the feeling, that by complying with the direction of the coroner, I should be doing injury to the profession through an injury done to myself. Besides, I object to be even a partial means of continuing the present unjust system. Whether I acted according to *law* I beg to be informed, and remain, Sir, your most obedient,

WILLIAM ROBINS, House Surg.

Western General Dispensary, New Road,
October 1, 1835.

. The only question of Mr. Robins to which we need reply may be thus answered:—He was not liable to the institution of any proceeding at law, for the infliction of any penalty, for refusing to open the body without remuneration.—Ed.

THE SYSTEM OF LECTURING.

To the Editor of THE LANCET.

SIR,—The truth of the remarks in the leader of a recent number of your invaluable publication, on the impositions of the lecture system, must be acknowledged by every one who has been compelled to doze over the wearisome and un instructive discourses called lectures, which are paid for on compulsion, at such an exorbitant price. What intellect can master and retain the matter of six or eight of these lectures delivered in one day? Thanks, however, to the untiring exertions of THE LANCET, the system is tottering.

For my own part I have often considered that the lectures which a student hears, obstruct, instead of assisting the student, in obtaining a knowledge of the mode of performing operations; for instance; the directions for conducting them are generally conveyed in the most vague manner, or the student is intimidated and prevented from attempting them, by alarming statements of the difficulties to be encountered. I am not the advocate of rash attempts, but I dispute the propriety of frightening students from attempting operations of any kind that may hereafter fall into their hands, instead of fully instructing them in their performance. I fear that the alarmists bear in mind on these occasions the effect of fully informing embryo practitioners on those points which hospital teachers and operators take especially under their own care as "pure" surgeons. Let the lecturers say what they like in favour of the lecturing system, I am sure that the pupil, especially when he is out of the pale of their influence, and with calm and dispassionate mind looks back on the system, will feel and acknowledge the entire truth of the remarks which THE LANCET has lately made on the subject. With an expression of satisfaction that you have drawn yet further attention to this system, and fully assured that when the system has been thoroughly purged, its insufficiency and unworthiness will be admitted by every one, I remain, Sir, your obedient servant,

MEDICUS.

Worcester, Sept. 29th, 1835.

MIDDLESEX HOSPITAL SCHOOL.

SIR C. BELL, in his introductory address on the opening of this school, remarked that it had been established in order to counteract the effect of a certain party, who had deprived of its name the *Middlesex Hospital*, the government of which were no sooner fully

informed of the fact, than they enthusiastically came forward and supplied the funds necessary to institute a medical school in connexion with the hospital. Sir Charles spoke of his connexion with the London University, and stated that the Council had refused to allow him to lecture on particular parts of the subject, alleging that it would not be just to other lecturers that he should have the privilege of lecturing on a "higher" branch of the science. He had contended, however, and still contended, that there was no such thing as a "higher" branch of anatomy, all parts of it being equally high and important. He considered that it was a bad plan for the University to have a professor and a demonstrator of anatomy, and this he told the Council at the beginning. The pupils, he said, would be more intimate with the demonstrator than the professor, and would regard the latter as too great a personage to be troubled with questions on anatomical points. Consequently the professor would be of hardly any use to the pupils; he would be a mere form, a name. Anatomy was not to be learned without the constant presence of the teacher in the dissecting-room, and he thought that the proper plan was for the teacher himself, the "professor" or the "demonstrator," whichever name they chose to give to the teacher, should put on the sleeves and apron, and demonstrate in the dissecting-room, as he (Sir Charles Bell) had done. Sir Charles spoke of the little influence he had possessed in the Council of the University, and said that everything he had proposed was rejected. Amongst other errors of the Council he placed the circumstance that the Council had wished to purchase a German museum of anatomy &c., at the price of 30,000*l.*, a measure which he opposed,—the Council, after the proposal had been postponed for a short time, finding that they had been about to bargain without having the money to pay for it. Sir Charles then spoke of his evidence before the Parliamentary Committee, and repeated his belief that knowledge was more rapidly acquired under disadvantages, and the mind more fully strengthened by having difficulties to overcome, than where the student had abundance of money to pay under the certificate system, and plenty of apparent facilities for acquiring knowledge. He cautioned pupils against expecting, under the existing system of medical government, to be rewarded according to their merits and industry. The greatest men, he said, had died poor, and some were even persecuted for their real eminence as scientific men, who having prosecuted their inquiries farther than the drones of the profession, had met with injuries instead of reward.

BLENHEIM-STREET SCHOOL.

THE lectures commenced at this establishment on the 1st of October, with an introductory address from Mr. King, the teacher of surgery. After examining the nature and intent of medical knowledge, and asserting its claim to be ranked as a science, Mr. King alluded to the importance of practical observation and strictly logical deduction. "If medical science," he observed, is founded so essentially on observation, does it not follow that the great requisite in the medical student, is a mind capable of careful, minute, and patient inquiry, and of sufficient logical power to draw correct inferences from the facts observed? The habit and capacity of right and rapid reasoning, is so necessary in the application of the rules of treatment to individual cases, that I would particularly insist on the necessity of cultivating logic and mental philosophy. Without these no man can be a good practitioner. It is the misuse of evidence at the bed-side as well as in the hall of justice, that is a fruitful cause of suffering. A medical man should be skilled in detecting fallacious reasoning as well as false facts. Patients are apt to deceive both themselves and their doctor. Errors are constantly arising from the confounding of cause and effect, from confounding the symptoms, which are effects, with the disease which is the cause of them, and from attending to localities only, instead of regarding the whole human structure, the mind never having been sufficiently trained to admit of its grasping in one conception the entire human organism. Besides, the exercise of the intellect to accurate reasoning and the understanding of mental phenomena, are the more incumbent, as the mind exercises, both in the healthy and diseased state, such an influence, that a man unskilled in mental, and, I may add, moral physiology and pathology, must be unable to detect the cause, and apply the remedies, of a very extensive variety of human suffering." Mr. King referred to the influence of public opinion upon the medical profession, and the change gradually made to render examinations for a diploma more complete. "In requiring guarantees for the security of the public by examinations which will test high qualities of mind, a thorough practical knowledge should be indispensable for the exercise of the healing art. The legislature should also imitate the governments of other countries in the protection and encouragement they extend to those who devote themselves to scientific pursuits. I could appeal to numberless instances of meritorious men, disheartened by the little reward they find for their arduous and sometimes perilous exer-

tions. Many a man has been heard to say, — 'Why should I toil; why labour through the long and dangerous researches of my avocation, to win the knowledge that does not allow me to live? Why penetrate the foulest adyta, why hang with idolatrous fascination over some mass of decomposition? Why make disease and all its loathsome characters the food of my soul, the friend and companion of my life, ay, the poetry and witchery of my most ardent enthusiasm, to pine neglected, unnoticed, and forgotten, while some ignorant charlatan is the object of popular favour and support?' Mr. King concluded by exhorting the pupils to be zealous and industrious. "If," said he, "we make ourselves well acquainted with medical science, we shall stand in the same relation to other classes of society, that our particular science bears to other sciences. And can there be a higher science than that which confers the power of preserving life and freeing it from disease? Can there be a nobler avocation than that of protecting and lessening from pain and debilitation our fellow men? I know of no greater interest on earth than the interest of human health; and the man who can lay claim to the merit of having contributed to the protection and advancement of that interest, is second to none of his species. He stands upon the proudest eminence upon which a man can stand; and commensurate with his usefulness ought to be the respect paid to his character. It is an eminence obtained only by much labour, by long perseverance, and through some danger; and proportionate to these should and shall be the reward of obtaining it. Yes; *should* be as far as the recompense can be conferred by society; and *shall* be, because that recompense which best accords with the pure and noble nature of his services, the practitioner derives from the conscientious exercise of his useful, his beneficent, his almost divine vocation. That is a reward which no earthly power can give, and which no earthly power can take away."

ST. GEORGE'S HOSPITAL.

INGUINAL HERNIA.

THOMAS WILLMAN, aged 25, was admitted into the hospital March 3rd, at 4 p.m., under the care of Mr. Walker. There is a tumour in the groin in the usual situation of inguinal hernia, of an oval shape; elastic in some parts and firmer in others; about three and a half inches in length and two inches in breadth; the general surface of the tumour is hard, giving the sensation of the feeling of omelette, and containing in it; but the external part of it is softer, with the exception of a small portion which is supposed to be the testis, and

which he says has never descended into the scrotum. The pain of the tumour is not very severe, even when roughly handled.

He states that he has always had a small tumour in the groin, and which he supposed was the testis. About three months since, whilst riding on horseback, he was thrown with some degree of force against the pommel of the saddle; this was followed by the appearance of a tumour in the groin (of nearly the same size that it is at present), which, however, subsided upon his lying down in the horizontal position, and this tumour did not return until about four days since, when, after using some undue exertion, it suddenly reappeared, and he has not been able to remove or reduce it since. He has taken several doses of aperient medicine, which have rather tended to aggravate the pain than otherwise. The swelling has not diminished, and he was bled without effect to two pints before his admission.

There has been constant sickness since yesterday morning, and no alvine evacuation for the last three days; pain and tenderness over the whole abdominal region, and a dragging sensation about the umbilicus. Pulse 140, small and weak; skin hot; tongue furred. On his admission he was put into the warm-bath, which produced syncope, and attempts were made by the taxis to reduce the swelling, but without effect. Ether was applied over the tumour, but no benefit resulted; the sickness and hiccup increased, the pulse rose, and the abdominal tenderness greatly increased.

Under these circumstances Mr. WALKER determined upon operating immediately. On laying open the sac a mass of dark thickened omentum, with a narrow neck, was exposed; beneath this was a small knuckle of strangulated intestine, and to the outside of all, the testes and epididymis were seen. Some little difficulty was experienced in dividing the stricture, from the chord lying in the way; this, however, was removed, the stricture was divided, and the intestine returned easily. A ligature was placed around the neck of the mass of omentum, which was then cut off, a pledget of lint was introduced into the wound, and sutures, strapping, and compresses, were applied.

10 p.m. He has had no sickness since the operation; pain in the abdomen less; but considerable tenderness remains; pulse 108.

R. *Sedative Solution of Opium* ℥xx; *Spirits of Nitric Ether* 3j; *Solution of Acetate of Ammonia* 3ss; *Camphor Mixture* 3j; to be taken directly. *Castor-Oil* injection to be administered every six hours until the bowels are open.

11. The bowels have been relieved seven

times during the night, and he slept a little in the morning. He feels easier. The abdomen somewhat full, but less tenderness present; pulse 110, sharp and compressible; skin cool. Mutton broth for diet.

8 p.m. The bowels have been relieved several times during the day; spirits rather low; pulse soft; less tenderness; no pain; tongue less coated.

R. *Aromatic Confection* gr. xv; *Tincture of Henbane* ℥xv; *Camphor Mixture* 3iss; every six hours.

5. He has passed a very good night, and is free from pain, except when firm pressure is made upon the abdomen. The tongue is cleaner and moister. The skin cool, pulse 80, and soft. The bowels have not acted since yesterday afternoon.

Towards the evening he complained of some pain on the left side of the abdomen, which was increased by pressure. The skin is hotter; tongue whiter; pulse 80, and sharp. The abdomen is distended, and the bowels have not acted for twenty-four hours. Twelve leeches to be applied to the abdomen.

R. *Carbante of Pulash* 10 grs.; *Sulphate of Magnesia* 1 drachm; *Syrup of Poppies* 1 drachm; *Distilled Water* 10 drachms. The draught to be taken every six hours.

6. He did not sleep much until this morning; there is less pain and abdominal tenderness, but some little irritation about the wound. The tongue is cleaner; pulse softer, 84, and jerking.

7. He is quite free from pain; skin cool; tongue moist; pulse 80, and soft. The dressings were removed for the first time since the operation; the upper half of the wound was found to be united by the first intention, and there was a little pus in the lower part of it.

8. He continues quite free from pain, and is doing very well in every respect.

10. He is doing very well. The wound has nearly healed, except at the lower part, where the ligature comes through, which is attached to the omentum. Mr. WALKER endeavoured to remove it, but failed. The bowels have generally acted twice in the twenty-four hours. Repeat the draught every six hours.

16. He has continued steadily improving since the last report; the wound has been dressed every day, but the ligature had not separated in the least until to-day, when it came away very easily in the dressings. The only part of the wound now open is that through which the ligature came.

21. The wound is quite healed.

26. A truss with a circular pad in the centre to admit the testis was applied, and keeps up the hernia extremely well. He was then discharged quite well.

SCLEROTITIS.

James Slight, *ætat.* 41, was admitted on the 28th of March, under the care of Mr. WALKER. From the facts which could be gathered in connexion with the previous history of the case, it appeared that on the 10th of the month, whilst employed in cutting wood, a chip flew into the right eye: severe pain ensued, which lasted for two days, at the end of which time he went to a surgeon, who ordered him a lotion for the eye. This did not abate the pain and suffering. On the 24th there were great restlessness and great heat of the skin, with increased pain in the eye, and a copious watery discharge.

On his admission into the hospital, the sclerotic coat was highly vascular, and its minute vessels were extensively injected; the cornea was less transparent than natural, and a minute ulcer could be perceived in the outer and middle part of it, into which, in consequence of its convexity, the iris appeared to protrude slightly. Around this ulcer could be seen a thin nebulous line of about one line and a half in breadth. There was great intolerance of light, with pain over the right temporal region. His general health has always been good, and is not disturbed at present. Tongue clean; bowels not open; pulse 64, full and soft; skin cool; sight of the right eye quite gone.

R. *Calomel* gr. ij; *Powdered Opium* gr. ss; every night at bed time. A Senna draught to be taken every other morning; eight leeches to be applied behind the right temple; a blister behind the right ear; extract of Belladonna over the right eye.

March 29. Eye very painful during the night. A saturnine lotion to be applied to the eye.

30. Twelve leeches to be applied to the eye.

April 1. To be cupped on the nape of the neck to twelve ounces. A ʒij Senna draught to be taken directly, and repeated in two hours, if necessary.

3. Continue the medicines.

4. There is still much remaining inflammation of the sclerotic, and much intolerance of light. The cornea is not more nebulous than before. The pupil is not quite circular, the external edge being depressed, as though the iris had become slightly detached from the ciliary ligament. At the inferior edge of the pupil there is seen a prominent opaque surface resembling lymph, which extends nearly to the inner surface of the cornea. Pulse is natural; skin hot; thirst and headache. Continue the medicines; omit the lotion.

10. The eye is very much improved, and the man can see very well; the sclerotic

and conjunctival coats are much less injected than at the last report. The iris appears in its natural state. The pupil is small but regular in its outline. The cornea is quite clear, and at the inferior border of the pupil in the anterior chamber there is seen an opaque body, which is the capsule of the lens. There is no pain in the head; he sleeps well, and the appetite is good. Continue the medicines.

16. The capsule of the lens is now seen to be adherent to the inner surface of the cornea, occupying a small portion of its central and inferior surface, and the inferior portion of the iris is, in consequence, drawn forwards. The lens appears rather opaque. There is not so much sight in the eye as before. There is still a circular zone of the bloodvessels to be seen around the lower edge of the cornea. He complains of no headache or intolerance of light. The general health is improving. The appetite is good.

Plummer's Pil gr. v every night at bed-time. Half a pint of the *Alkaline Infusion of Sarsaparilla* to be taken daily. Ordinary diet.

May 4. *Calomel* gr. iv at bed-time. A senna draught to be taken early to-morrow morning.

5. On visiting the patient to-day, Mr. WALKER, under whose care he was admitted, passed a needle behind the iris into the posterior chamber of the eye, with the intention of depressing the capsule of the lens, which had become dissolved in the aqueous humour by the rupture of the capsule at the time of the accident, and it was by this means removed as much as possible out of the immediate sphere of vision.

R. *Saline Draught* ʒi ss; *Solution of Tartrized Antimony* ℥xv; *Sulphate of Magnesia* ʒi; every six hours. Twelve leeches to the right temple.

May 13. He is very much improved, and can see distinctly with the eye; there is neither pain nor intolerance of light; the pupil is still small, and is slightly opaque; general health good. Continue the medicines. Ordinary diet.

18. Discharged cured.

NORTH LONDON HOSPITAL.

POISONING (?) BY ACETATE OF LEAD.

LOUISA WALLACE, aged 19, was admitted August 25th, under the care of Mr. T. THOMSON. An hour after her admission she had taken two pennyworth of sugar of lead, for the purpose of purging herself, to which act she was prompted by desire

tion. She thinks that the quantity of acetate of lead was about an ounce. She dissolved it in a cupful of water, and after drinking it, waited on the step of a door for its effects. In about a quarter of an hour violent vomiting came on, which attracted the notice of two men, who inquired of her what was the matter. On being told she had taken poison, they brought her to the hospital. Mr. TAYLOR, the apothecary, immediately gave her half a drachm of the sulphate of zinc in solution, which was soon after repeated; this renewed the vomiting (which had almost ceased) as violently as ever, and after continuing for upwards of an hour, very dilute sulphuric acid was administered, and she was put to bed. She complained of slight burning pain in the stomach, which, however, did not prevent her from passing a good night. Mr. TAYLOR ordered her in the morning a draught composed of sulphate of magnesia, half a drachm, and an ounce and a half of water, to be taken every second or third hour, which acted slightly on the bowels; she then complained of weight in the head, some dimness of sight, and pains shooting through the eyeballs on closing the lids firmly. The tongue was clean, or nearly so; the pulse sixty and small. There was more pain in the stomach on the following morning (26th) than before. The following treatment was ordered:—Twelve leeches to the epigastrium; one grain and a half of the Extract of Opium at night; increase the Sulphate of Magnesia to a drachm.

27. There is tenderness on pressure all over the abdomen, but especially at the epigastrium, where it causes her severe pain. Continue the medicines.

28. There is now no pain or sensation of heat in the stomach, and she can take food without uneasiness. The tongue remains somewhat white. The pulse is 80 and weak.

29. She feels quite well; the tongue is clean; the strength returning.

30. Discharged cured.

Dr. THOMSON pointed out to the pupils the features in this case which prevented it from being regarded, in the strict sense of the word, as a case of poisoning. The vomiting which occurred was the effect of quantity; the salt acting in the same manner as a large dose of common salt, from its irritant quality, and not from any real poisonous property belonging to it. In small doses, namely, under ten grains, Dr. THOMSON had never seen any deleterious properties arise from the acetate of lead, unless saline effervescent medicine was given at the same time; in which case, the acetate was converted into the carbonate, which is a powerful sedative poison; and according to the doctrine promulgated by the professor, and founded on numerous experiments made on animals, the only poison among the

salts of lead. "When the acetate or subacetate proves poisonous," he observes, "there is always a conversion of the salts into the carbonate; and inasmuch as the subacetate is more easily converted into the carbonate than the acetate, so it is more likely to prove poisonous, a fact which experience has corroborated. Several instances are recorded in which death has resulted from swallowing Goulard's lotion by mistake; and even of paralysis having followed its external application to large abraded surfaces, but in all these cases the deleterious effects could be traced to the conversion of the subacetate into the carbonate." The administration of an emetic after the vomiting that occurred, Dr. T. did not regard as absolutely necessary, but had no vomiting taken place, then the sulphate of zinc was the best emetic that could be administered, because it decomposes the acetate of lead in the stomach, and converts it into an insoluble, and, consequently, into an inert sulphate, whilst the acetate of zinc, which is also formed, is as active an emetic as the sulphate of zinc. The administration of the sulphate of magnesia operates, also, by decomposing the salt of lead; and the acetate of magnesia that results from this decomposition, carries the insoluble sulphate out of the bowels. The food which is ordered in these cases, should be of a kind not likely to generate carbonic acid in the stomach, and it is a good thing to order vinegar as an article of diet, for two reasons, namely, the lessening of the susceptibility to decomposition of the acetate, owing to the presence of the surplus acetic acid, and the formation of a portion of it into the sulphate, by the small quantity of sulphuric acid which all vinegar for domestic purposes contains. On this account, however, when the acetate of lead is ordered in cases of internal hemorrhage, the distilled vinegar, not the common vinegar, should be given at the same time. There is a case at present in the hospital, in which paralysis of the wrists was caused by working with white lead, which is a carbonate, although no colic had preceded or accompanied the paralytic affection. The patient is a painter. This local influence of carbonate of lead is not confined to painters; it is experienced also by compositors in printing-offices, and porters in lead warehouses; and in both cases, the deleterious cause is the carbonate, which forms on the types after they are washed, and which affects the compositor in distributing the types to their proper places in the cases. It also forms on the type in the composing-room by the combined action of air and moisture, the latter being often freely supplied, to cause adhesion at certain times between the types.

ST. BARTHOLOMEW'S HOSPITAL.

MR. STANLEY'S INTRODUCTORY LECTURE.

MR. STANLEY delivered an introductory lecture to his sessional course of anatomical lectures, on the first of October, to an audience not quite so large as that which used to assemble in the theatre of this hospital. He commenced with a sketch of the constituents of the human body, in order, as he said, to secure the attention of his auditors, and in consequence of the intimate connexion of the subject with the study of medicine. With much novelty he adverted to the skeleton as the basis upon which the soft parts were constructed; the cranium, by its arched and conical configuration, affording a beautiful protection to the delicate brain; the ribs forming an important enclosure for the thoracic organs; the pelvis sustaining the weight of the body, and holding structures of vast consequence; while the foot, by its arches, admirably discharges the duty of a foot—the whole skeleton yielding illustrations of every valuable discovery that had ever been made in mechanical science. He referred to a section of the femur, to show the difference between external and internal osseous structure. The powers that acted on the bones, namely the muscles, were, he observed, exceedingly interesting to the student. Their force was actually astounding. Dr. Young computed muscular power to be equivalent to five hundred pounds on each square inch of its acting substance. The celerity of motion of the muscles was no less remarkable. Haller asserted that he could articulate fifteen hundred letters in a minute. Immensely important also was the nervous system, so intimately concerned as it was with the reasoning faculties. The senses were really all dependent on the nervous system. Yes, sight, sense, touch, and hearing, all resulted from a peculiarity in the function of particular nerves; the senses acted as monitors against danger. The human eye differed from that of the brute by indicating intellectual feeling, whereas in the latter its expression merely denoted a desire to gratify appetite. Physiologists have observed that in proportion as one sense is impaired, the remaining senses increase in acuteness. A blind man, for instance, has ascertained his proximity to objects by the reverberation of the air on his ear. The vascular and absorbent systems were next reviewed, in an equally new and striking manner, as means of reparation, especially in the osseous reproductions that succeed necrosis of the long bones. The absorbent vessels, however, he observed, were so obstinate, as to entertain an objection to remove some description of matter, such as vermillion and charcoal, which, when inserted beneath the cutis, remained indelible.

Nitrate of silver afforded another confirmation of this fact. The subject of fetal gradation was handled with no less ability and originality. The *fetus*, it was observed, in its progressive gradations, bore a close analogy to the gradation upwards of various species of animals. As to the variations from natural appearances which occasionally arise, these with singular ingenuity were said to arise from an interruption in development, as in the hare-lip. Mr. STANLEY concluded by enforcing the absolute necessity of studying surgery thoroughly, in order to understand it thoroughly, the utmost diligence and enthusiasm of students being necessary under the existing system of instruction, which Mr. STANLEY said nothing to depreciate. No hiatus in fact, he added, should exist in his (the lecturer's) assiduity to impart information, and he doubted not that his efforts would be successfully repaid by the unremitting attention of such a class as he might have the honour of obtaining.

WOUND OF THE INTESTINES FROM EXTERNAL INJURY.

JOSEPH SHAW, *æt.* 17, was admitted into Harley's ward, St. Bartholomew's Hospital, on the 26th of August, under the care of Mr. EARLE, with an injury in a situation midway between the crista of the ilium and the false ribs on the right side, inflicted by the shaft of a cart thrusting him in contact with the wall. He complained on admission of severe vomiting and faintness; the urine exhibited a bloody tinge; there was considerable uneasiness encircling the locality of the mischief, with a central depression. Mr. EARLE considered, from the seat of the injury, that the kidney or colon might have been involved, but he was more inclined to ascribe it to the former, on account of the sanguineous character of the urine. Considerable tenderness in the affected part becoming evident, twenty leeches were applied, and he was cupped on the loins. The central depression having become more evident, Mr. EARLE was led to form an opinion that the abdominal muscles in that situation had undergone rupture, and that a portion of intestine had thereby become protruded; the latter part of his prognosis was further confirmed by a gurgling sensation communicated on the application of the hand, and by the swelling receding under pressure; from this view of the case he entertained an idea of employing a truss, but was exceedingly surprised, after a lapse of two or three days, to hear that an abscess had formed, its contents, consisting of pus and feces, having made their exit by three small openings. Mr. EARLE now ascertained that not only the abdominal muscles, but also the portion of the ascending colon, covered by peritoneum, had been ruptured in the patient's

salvation was purely dependent on the injury not implicating the cavity of the abdomen, commonly so called; the ruptured intestine being uncovered by the serous investment, precluded the extravasation of feces into the peritoneal sac, which (had it occurred) must inevitably have been attended by fatal results. Mr. EARLE observed that there were many exceedingly interesting details to be found in the *Mémoires of the French Academy*, where sharp instruments, such as swords, had perforated the intestine, and nothing unfavourable had resulted. This Mr. EARLE considered very probable, especially when the intestine was in an unloaded state, and where no effusion had supervened; but the case differed widely in which the intestine had been actually ruptured from severe injury. The course of treatment that had here been adopted was to dilate the openings to permit of a freer egress of purulent and feculent matter; this procedure it was thought there would be a necessity to repeat; the lower bowel was daily relieved of its contents by means of a clyster, with a view, as it were, to invite the feces to their natural outlet; this plan had been so far successful that although some excrement passed through the aperture, yet a considerable quantity had already resumed an ordinary route. The *ensemble* of the patient seems to augur favourably.

ANEURYSM OF THE SUBCLAVIAN ARTERY.

A case presents itself in Barker's ward which is well worthy the attention of medical practitioners and students. The subject is a man whose name is Joseph Webb, æt. 42, who was admitted into the hospital on the 21th of August with a large aneurysmal tumour projecting from beneath the right clavicle, and extending outwards; its magnitude approximated to that of a child's head, and it was adjudged by Mr. LLOYD, under whose care he was admitted, to be an aneurysm of the subclavian artery. At some little period from his admission a day was appointed for performing an operation (that of tying the subclavian artery); but in consequence of circumstances occurring connected with the patient's general health, its postponement was announced at the expected period of performance. General depletory measures have been resorted to with favourable results. Digitalis has been used but for a very limited period; venesection has been employed, and its employment repeated; the strictest quietude has been enjoined; and under this palliative mode of treatment the patient has manifested progressive improvement; his aspect has become more cheerful; the size of the tumour has experienced considerable diminution, and he experiences no inconvenience, except that he is unable to sit in an erect position. It is understood that no further idea of ope-

rating exists with Mr. LLOYD. The case is interesting, inasmuch as it exhibits a provident effort on the part of nature to repair organic lesions, when aided by the employment of remedial treatment. The foregoing report was taken on the 27th Sept. 1835.

AMPUTATION BELOW THE KNEE.—Thomas Trott, æt. 58, a waterman at a coachstand, was admitted on the 21th of June with a severe injury of the right leg, consequent on ejection from a cab, the wheel having passed over the inferior portion of the limb, on the internal surface of which there appeared a slight ulceration, to which succeeded erysipelas of the entire member. Leeches, and saline medicines, with tartar emetic, and other means calculated for the preservation of the limb, were employed in vain, and amputation was deemed absolutely necessary, the operation being performed on Tuesday the 25th of August. Previous to the operation some doubts were entertained as to whether fracture really existed in the vicinity of the ankle-joint. Mr. EARLE commenced the flap amputation six inches below the knee-joint; the flap was then completed, and the catgut was used to divide the muscles and interosseous ligaments, the sharp upper ridge of the tibia being sawed off previous to the division of the bones. The rest of the operation was conducted in the ordinary manner. An elaborate dissection of the diseased joint was afterwards made, but not the slightest evidence of fracture was discovered. All the cartilages covering the tarsal bones had undergone absorption; in fact, the bones were literally denuded of cartilage, a circumstance which, in the opinion of the surgeons present, resulted from inflammation consequent on the injury, the constitution of the patient being a bad one.

HYDROCELE.—Mr. STANLEY performed the operation for hydrocele on a man who had suffered under the affection for three months. The quantity of fluid evacuated was considerable. The injection used was a mixture of port-wine and water, but Mr. STANLEY observed that he had known instances where the re-injection of the evacuated fluid, or even the introduction of pure water, had been attended with eminent success. The most unexceptionable and definite form of injection, however, consisted in a solution of the sulphate of zinc, a drachm to a pint. The nature and quantity of the fluid injected were immaterial considerations; but it was of paramount importance that the injection should be brought into immediate contact with the morbidly secreting surface, the time of its retention varying with the peculiarity of the case, the production of a certain amount of irritation indicated by a certain amount of pain. In

the present case it would be judicious to permit the patient to remain in the ward with a view to relieving the occurrence of irritation (which here had been somewhat protracted), rather than allow him the quietude of bed. The two most important points in operating for hydrocele were, first, to avoid puncturing the testis; and, secondly, to select carefully the part for the introduction of the trocar instrument, to obviate the liability of wounding one of the large veins traversing the scrotum, as in the event of such an accident the blood would become effused into the scrotum, and what was at first a hydrocele would then be converted into a hematocele.

ACUTE BRONCHITIS.—Patrick Thornton, *at.* 30, was admitted into Matthew's ward, on Tuesday the 21st of July. On the day of admission the following were the symptoms:—Countenance dusky; lips parched; the temperature of the surface augmented; no cuticular transudation; pulse 124, and compressible; tongue covered with a thick white fur and rather dry. He complains of a short cough attended by great pain, extending from the third to the sixth rib of the right side; he cannot effect a deep inspiration, and lies on his back; the alvine excretions are daily induced by medicine; anorexia and much nausea; the urine high-coloured and scanty; no cephalic pain; perfect absence from abdominal tenderness; sleep considerably perturbed. A small quantity of blood was this morning ejected from the mouth; the expectoration has a frothy and a streaky aspect. He had enjoyed tolerably good health previous to last Friday, when, after dinner, he was suddenly seized with a pain in the chest, accompanied by difficult respiration; his skin then became hot and his bowels constricted. He applied to the parish surgeon, who prescribed some purgatives, and a sinapism to the chest. Auscultation ascertains more air to enter the left lung than the right; crepitation mingled with sibilus and ronchus is evident in both lungs, anteriorly and posteriorly, but more especially in the left lung, as this admits of more permeation than the right. *Ordered twenty leeches and an emetic; and calomel with James's powder every second hour.*

22. Four ounces of buffy blood were taken from the arm by venesection, half an hour after which the ingress of air into the right lung was more free, the pulse quickened, and the respiration was easier. *Cupping to four ounces beneath the right scapula; a blister; a grain of calomel every hour.*

23. Thoracic pain entirely gone, and the patient in all respects better. Some sibilus still audible. The medicines to be discontinued.

24. Lips more livid; ronchus and sibilus equally diffused throughout both lungs. the left lung admits less air than yesterday;

the right lung allows the entrance of less air in front than the left, in which Situation the crepitation is mixed with roushus and sibilus. Pulse more full and hard, computing 120. *Take ℥vj of blood from the arm.*
Solution of the Acetate of Ammonia.

26. Better; but slight permeation through the right lung.

27. No pain on effecting a deep inspiration; pulse computes 120. Little air enters the left lung; the right permits of a liberal ingression.

28. An increased quantity of air permeates the left lung, accompanied by ronchus. Ordered the *Hydrargyrum cum Creta*.

29. Mending. A free passage of air through both lungs, together with roushus. *Administer the Effervescent Draught.*

August 3rd. Sibilus is still to be discerned in both lungs, especially at the inferior posterior portion. Patient says he feels quite well.

10. Crepitation is audible over the whole posterior division of the left lung during inspiration, and likewise beneath the clavicle ; in which last situation he complains of pain on a deep inspiration, coughing, or lying on his side. The right lung is apparently quite healthy. No cough, expectoration, fever, or sweating.

11. The crepitation so diminished that none can now be detected. Discharged cured.

BOOKS RECEIVED.

Remarks on the Theory and Treatment of Scarlet Fever; with brief notices of the Disease, as it prevailed epidemically at Bridlington. in 1831. Hingley, 8vo, pp. 48.

A popular Treatise on Diet and Regimen; intended as a Text Book for the Invalid and the Dyspeptic. By W. H. Robertson, M.D. pp. 251. Tilt.

Leach's Selections from, and Translation of those parts of Gregory and Celsus, which have been fixed upon at Apothecaries' Hall, for the Examination of Candidates. pp. 332. Highley.

We shall next week make known some of the plans for adding to our usual mass of information, which we have formed with a view to the increased interest and instruction of the readers of *THE LANCET*, in the ensuing yearly volumes of this journal.

CORRESPONDENTS.

We have usefully availed ourselves of the introductory remarks of H. but have withheld the practical questions which he has given on a number of occasions because the means were not afforded of giving them the authority of a name.

THE LANCET.

Vol. I.]

LONDON, SATURDAY, OCTOBER 17, 1835.

[1835-36.]

In the present Number of THE LANCET will be found a guide to THE MEDICAL SCHOOL AND HOSPITALS OF INSTRUCTION IN PARIS, for the Session commencing in November 1835, and ending in August 1836.

THE RESPIRATORY APPARATUS IN OLD PERSONS.

THE *Archives Generales* for August contains an article entitled "Clinical Researches into the Diseases of Old People, conducted at the Hospital of Salpêtrière, Paris; by M.M. HOWMANN and M. DECAMPBRE, internes."

THE diseases peculiar to persons advanced in life have hitherto been sketched in a very slight manner by a few authors, rather than examined with that degree of care which they really demand. It would seem as if physicians thought the lamp of life at this period was too feeble to require any fostering attention, and that all that was necessary to be done was to allow it to burn out quietly without any attempt being made to prolong an existence, which, in the order of things, must very soon arrive at its termination. We do not want for treatises on the diseases of the infant state, or childhood: the maladies of adults have given rise to works without number, but we possess little clear knowledge, either on the modifications impressed by age on the texture of our organs, or on the functions connected with them.

The object of the authors of the memoir now before us is to supply this deficiency, and they commence with diseases of the respiratory organs, which, though frequently in old persons, assume certain forms which may deceive even the most experienced examiners. The observations on which the remarks are founded were made on the males of the Hospital Salpê-

trière, whose ages vary from 60 up to 90, or beyond 90 years.

Let us first notice a few anatomical circumstances peculiar to the respiratory apparatus of old women.

Thorax.—The thorax in aged females presents two states, very different from one another, which deserve to be examined.

The first is a case of exception, and found in aged females who conserve a considerable share of the freshness of youth; the mammae are voluminous and still consistent; the whole thorax is covered with a layer of fat; the muscles are well-coloured, and the costal cartilages retain their suppleness. However, the ensemble of the thorax has undergone a peculiar change belonging to old age; the superior part is flattened laterally in such a way that the antero-posterior diameter is considerably increased at the expense of the transverse one. This change is commonly accompanied by a gradual enlargement of the thorax towards the inferior part, which then represents a pyramid with a large base, whose apex has been somewhat shortened.

The second type is much more frequent. Here the cavity of the thorax is remarkably modified, and the lateral flattening above noticed may be carried to an extreme degree; in some cases it produces an angular form of the thorax, exactly like that seen in rachitic persons. This disposition of the chest is important to study, for it brings with it several changes in the relation and conformation of the subjacent viscera, which have not as yet been noticed by writers. Thus the liver is considerably pushed down from its natural position, and frequently bears the marks of pressure exercised on it by a narrowing of the inferior portion of the thorax, in females who have worn stays. In these cases also, the right lung is elongated, and follows the displacement of the liver into the abdominal cavity. The sternum is, as we mentioned, always carried forwards, but

the xyphoid cartilage is pushed backwards, and even sometimes completely concealed behind the cartilages of the last true ribs. The longitudinal diameter of the thorax also undergoes a remarkable change in old persons. This circumstance has been noticed by all writers. Sometimes the intervertebral cartilages disappear completely. Fischer* relates one case of a man aged 100, in whom nine vertebrae were reduced to one solid piece, and Boerhaave† met a similar alteration affecting the whole spine.

The vertebral column however is not only shortened, but becomes flexed forwards, and that often in a permanent manner. In consequence of the weakness of the dorsal muscles, the pressure is most felt anteriorly, and here the bodies of the vertebrae are most intimately united. This inflexion usually occupies the last cervical and first dorsal vertebrae, and is often carried to an extreme degree; in some of the old women at Salpetriere it is so marked, that the posterior surface of the scapula becomes superior, and the cervical region makes nearly a right angle with the dorsal. The changes just pointed out in the external form of the thorax, must necessarily occasion corresponding alterations in the viscera contained within its cavity, or connected with it. The diaphragm is thrown into folds, which in some cases leave their mark on the liver, and this viscous is pushed down into the cavity of the abdomen several inches below its natural level; the tissue of the ribs themselves is much rarefied, but (contrary to the assertion of authors) in a very few cases only do we find an osseous incrustation of the cartilage of the ribs. The costo-vertebral cartilages generally conserve their mobility to the most advanced period of life.

Lungs.—Before we pass to the pathological examination of an organ, we should possess correct notions of its structure at the period to which our examination is limited, for the former cannot fail to receive special characters from the latter. Hence it is of great importance to study the structure and peculiarities of the pulmonary tissue in old persons. With respect to their external configuration and appearance, the lungs of old persons may be ranged under three classes.

In the first, the lungs preserve nearly their normal aspect, and differ very little from those of the adult; however, in all cases where the chest presented a lateral flattening to any considerable degree, the authors found a peculiar disposition of the interlobular fissure. This becomes vertical, in such a way that the two lobes of the left lung are opposed to each other, one directly forwards, the other backwards; while in the right lung, the middle lobe, directed downwards, is surmounted by the inferior lobe, which in

some cases even constitutes the posterior quarter, or those of the summit of the organ. Hence a pneumonia of the summit may occupy the inferior lobe, as we shall presently have occasion to see.

In the second class, the peculiarity consists in the smallness of the lungs. The organ is light, and little susceptible of being inflated by the greatest force. They are constantly bathed in the cavity of the chest by a limpid serosity; when compressed, their crepitation is more diffuse than in the lung of the adult.

In the third class the lungs present a mass unequally thrown up into eminences, and are bathed in a much greater quantity of fluid; they are flaccid, livid, and have altogether lost their conical form. The division of the lobes is not less remarkable; the latter are merely united by a flat, thin pedicle, which leaves them as it were floating in the thorax; they are extremely light, and give a most peculiar sensation to the touch; the heart is smaller, and often in a state of complete anemia; the thorax is excessively emaciated.

Intimate Structure.—M. Magendie, who has made some interesting researches on the structure of the lungs in old people, lays it down as a fundamental rule, that the air-cells are increased in magnitude, giving rise to a considerable diminution of their specific gravity. However, the exaggeration of the cellular structure is only perfectly seen in those persons who present the traces of old age in a very high degree. The lungs of aged persons were examined by our authors nearly in the same manner as by M. Magendie, but they had not recourse to insufflation. They arrange the lungs, considered as to structure, under the three classes above enumerated, viz.

1st. Case. "Lungs voluminous, filling a thorax well developed, and whose soft parts are still free from emaciation, or even fat." A thin cut of this lung dried gives a number of holes perfectly round, crowded together like the meshes of lace, and presenting a diameter of about a quarter of a line. (Fig. 3.) The cells are here perfectly regular, and everywhere independent.

2nd Class. "Lungs of regular form, but small, bathed in serosity; thorax contracted; soft parts emaciated." A thin cut of this lung dried, shows a texture somewhat similar, but differing in many respects. The cells are no longer round but elliptical, and the vascular apparatus is less numerous; the cells, however, are still limited by a regular circumference, and are independent. (Fig. 4.)

3rd Class. "Irregular form of lung, which is withered-looking, and applied to the vertebral column; the thorax is contracted, and reduced to an extreme degree of smallness. Here the pulmonary tissue does not present any distinct form; the substance is converted into a sort of sponge, and the microscope distinguishes a few scattered cells."

* Tractatus de Senio ejusque Grailibus et Morbis.

† Prælect, tom. III, p. 725.

ches, and there is no trace of the lobular subdivision. This latter condition of the lung, which is always found in persons presenting the characters of old age in a well-marked form, is a species of natural emphysema which is well worthy of attention, but it is necessary not to confound it with morbid lesions, properly so called.

If we compare the relative sizes of the pulmonary cellules in the infant, the adult, and the aged person, we shall find a remarkable progression as we approach senility. This has been proved by the author, in frequent experiments. Thus the dried cells of the infant lung are only a twelfth of a line in diameter (fig. 1); those of the adult about

one-eighth or one-sixth (fig. 2); finally, the diameter of the air-cell in the aged (fig. 3), presents a diameter of one-fourth of a line. Hence the law first pointed out by M. Magendie, that the pulmonary tissue becomes rarefied directly in proportion to age.

Such is a brief anatomical history of the structure of the thorax and lungs in aged persons; in a second memoir the authors propose to take up the physiological part, and treat "on respiration in old patients." We shall not fail to follow their observations, which promise to bring to light several new and interesting facts.

Explanation of the Engravings.—The air-cells may be supposed to occupy the entire surface of each layer.

No. 1. Layer of the lung of a child four years of age.

No. 2. Layer of the lung of an adult female.

No. 3. Layer of the lung of an old female

(first type). Commencement of rarefaction in the lungs; cells round, but quite independent.

No. 4. Layer of the lung of an old female (second type). Second degree of rarefaction; cells elliptical, but still independent.

No. 5. Layer of the lung (third type). Extreme degree of rarefaction. Irregularity and fusion of the cells.

REFLECTIONS ON

INFANTILE REMITTENT FEVER.

By JOHN ALEXANDER, M.D., Manchester.

(Continued from page 411.)

CASE 2. May 21st, 1832.—Thomas Wood, aetat. 4, from Queen-street, admitted a home-patient of the General Dispensary for Children, presents the following symptoms:—Extreme emaciation with a rough dry skin; tickling cough, with little or no expectoration; tumid abdomen, with bowels irregular, though generally constipated; total loss of appetite; much thirst; great irritability; constantly picking at his lips, nostrils, or other parts of his face; cervical glands enlarged; tongue reddish and dry; pulse 120. The boy's spinal column presents a double curvature in the scapular and dorsal regions. His mother states him to have been ill for two months, and to have taken worm medicine, occasionally to be flushed, and experienced fits in an evening, with occasional delirium during the night.

I have directed a domestic enema immediately; four grains of Dover's powder, with three of calomel at bed-time; and the tincture of iodine in camphor mixture during the day.

23. The enema was followed by one dejection, tolerably copious, of clayish-coloured scybala; but the bowels have not since been moved. The boy has had two very restless nights and an increase of delirium; his ancles are to-day observed to be swollen; pulse 140, and very weak. He refuses his mixture and all food, is unwilling to answer any question, and is obviously sinking. Recommended an occasional repetition of the enema, and the application of a blister to the nape of the neck.

25. Child died last night; permission to inspect obtained.

Section Cadaverica.—Body most strikingly emaciated, with the exception of the tumid abdomen. Skin of a dry, shrivelled, yellowish appearance.

Chest.—About an ounce of serous fluid between the pleura, with slight adhesions, apparently recent, on the left side. The lungs here and there studded with groups of tubercles some in a softened, but most

of them in a hard state. At the root of one of the left pulmonary lobes, a small vomica containing scarcely half an ounce of purulent fluid.

Abdomen.—Great distention; liver considerably enlarged, of a darkish hue, and unusually lacerable. The mesenteric glands are more than double their usual size; some of them contain a cheesy sort of fluid, whilst others appear to be filled with pus. There is no evidence apparently of recent inflammation in them; intestines much filled with air, not offensive on evolution; and containing, in the colon particularly, a considerable quantity of the same scybalous whitish feces ejected during life. In the ileum, on its mucous lining, are observed several small ulcerative patches about the size of a sixpence. The other abdominal viscera appear tolerably healthy; the peritoneal envelope considered thicker and more opaque than usual.

Remarks.—From the appearances noted within the thorax, this boy had evidently laboured, previous to my seeing him, under a more or less severe attack of pleuritis, conjoined with some tubercular inflammation. It is, however, anything but infrequent to find in those who have died from infantile remittent fever, clusters of tubercles under various conditions in the pulmonary parenchyma; and hence has arisen a very natural opinion amongst pathologists, that a strumous diathesis is the most frequent remote cause of infantile remittent fever, as it assuredly is of tubercular phthisis.

It will also be remarked, that the liver was found enlarged, of a darker colour than usual, and exceedingly lacerable. Reflecting on the general symptoms of the disease under consideration, it would by "a priori" reasoning be natural to expect, that more or less affection of that important viscus would present itself on autopsy. And, this is the case; for in the majority of fatal cases of this malady, when an inspection was not declined, alterations in size, colour, or structure, have almost invariably been observed by the present writer; and, on that observation, he has naturally been led to found his high opinion of the remedial influence of mercury in the complaint.

It is scarcely two months ago since I inspected (with the assistance of Mr. Walker, a scientific surgeon of this town) a boy about nine years of age, who had gradually sunk under infantile remittent fever in its most chronic form. After observing the ordinary appearances consequent upon the complaint, we were somewhat surprised to find the whole distal portion of the right lobe of the liver converted into a sac containing several ounces of purulent matter, and the parenchyma of that viscus quite lacerable: two evidences of advanced hepatic disease, which, considering the simple habits

of a child, and reputed insensibility (comparatively speaking) of the liver, are perhaps best accounted for by reference to the specific strumous virus above alluded to.

CASE 3.—June 13th, 1835. Master A—, ~~etate~~ nine, residing at Astley, near Leigh, brought to Manchester this day by Mr. Newton, an intelligent practitioner of the former place, who states as follows:—The boy has been delicate from infancy, but more particularly of late has been losing flesh in a marked manner. He has been, on one or two occasions, treated for worms, but has never been known to part with any, or to benefit by vermifugine remedies. His nights are very indifferent; he has great thirst, little appetite, no action of the bowels without medicine. On examination I find the boy extremely emaciated; his countenance pallid, with dark areolæ around the eyes; tongue whitish, with red elongated papillæ, numerous prominent; abdomen hard and tumid; pulse 118. Mr. Newton adds "that there is a febrile exacerbation each evening with succeeding morning chilliness, and has been for some weeks, and that the boy is indisposed to any, even the slightest exertion."

We have directed him to have a warm-bath on reaching home; ferrum tartarizatum with soda at bed-time, and castor oil each morning; his diet a milk one.

19. Mr. Newton writes, "I regret to inform you our little patient is much worse, the symptoms being considerably aggravated. On visiting him this evening I observed as follows:—Pulse quick and weak; tongue rather red at the tip and edges, and coated at the centre and back part with a white fur; bowels still irregular, and feces scybalous; urine high-coloured, but in fair quantity; thirst still great, and no appetite; skin moist; he refuses his medicine; is much reduced." The child's father adds, "that, in consequence of a pain suddenly arising in the boy's bowels yesterday, four leeches had been applied, and a domestic enema used."

20. Visited Master A. this day, in consultation with Mr. Newton of Astley, and Mr. Pendlebury of Leigh. The abdominal pain has been mitigated by the leeches, but is still complained of, aggravated on pressure; the boy's general appearance very unfavourable, from sallowness of complexion and great emaciation; pulse 112, weak; urine scanty and high-coloured; appetite none; thirst very great; tongue coated but moist; the bowels very much relieved by copious dejections of clay-coloured scybala after the enema of yesterday and the previous:—

Applic. Emplast. ven. A' minor
Repet. Enema domestic
Habt. gr. x. Hyd. c. Croc. 300

26. "The abdominal uneasiness," writes Mr. Newton, "was much relieved by the blister, and little or no pain is now complained of on pressure. The bowels continue very inactive, and the character of the evacuations unchanged. The tongue however is cleaner and moist. I attempted the addition of a little ipecacuanha to the evening powder, as we had agreed upon, but its nauseous taste prevented the boy's taking it. His pulse is somewhat reduced in frequency." Desired to continue the treatment.

July 10. The child improving. Bowels still torpid, but the motions *tinged* with bile. A little appetite, less thirst, and able to sit up in bed. Recommended an addition of a single grain of calomel to the evening powder, the latter and enemata being persevered in.

24. Much improved; abdomen lessened and soft; strength returning and fever gone; stools still figured, but of tolerable colour. Directed to have small doses of the sulphate of magnesia rendered palatable by nitric acid.

Aug. 15. Our patient progressing favourably.

25. Convalescent.

Remarks.—In the above case several modifications of diet were tried, such as stewed prunes, oatmeal with treacle, ripe fruit, buttermilk, &c., with a view to induce liquid evacuations; but the bowels, although so supplied and daily stimulated by enemata, continued torpid, and the feces figured, up to the period of convalescence; a circumstance somewhat unusual, considering the dejections had in a great measure recovered their bilious hue for some time previously. Again; this boy took, as may possibly be remarked, an extremely large quantity of mercurial medicine, upwards of three hundred grains of the hydrargyrum cum creta, independent of the calomel, and yet no perceptible affection of the salivary glands was induced by it! It has indeed, in several examples of infantile remittent fever, and in a few cases of acute rheumatic fever, been matter of surprise to the writer, how little the mouth has seemed to be affected by this useful mineral; whilst, in some other diseases, the reverse condition cannot have escaped remark: for example, during the decline of measles, wherein I have known the exhibition of a couple of ~~or three~~ doses of calomel, followed by consequent ~~or~~ *like* ~~the~~ *calomel* to the health of the patient, and ~~the~~ *calomel* of the practitioner.

(to be continued.)

PULMONARY APOPLEXY.

To the Editor of THE LANCET.

SIR,—The following case of pulmonary apoplexy happened in my practice at the City Dispensary; it presents some symptoms of very rare occurrence, which you may probably deem worthy of record in your useful Journal. I am, Sir,

Your obedient servant,

R. ROWLAND, M.D.

69, Fenchurch-street,
Oct. 12, 1835.

CASE.—Sept. 21, 1835. Thomas Holloway, aged 50, a porter, had been subject to cough and dyspnoea for several years, but he was able to work at his business until about two years ago, when the "shortness of breath" obliged him to discontinue all active employment. In general the cough and expectoration were trifling, but they were frequently increased from slight causes.

About a week ago, after exposure to wet and cold, he was attacked with an aggravation of all his symptoms; the cough became severe, the dyspnoea urgent, and the expectoration copious, but without any admixture of blood. The respiration was inaudible over the right lung, and was bronchial, with sibilant and mucous rale over the left; the heart's action could be readily distinguished over the whole anterior portion of the chest. On Thursday, the 17th of September, I received a hasty summons to visit him. During the previous night he had vomited an enormous quantity of blood, some of which was coagulated. I found him lying on his back; the pulse was quick, jerking, and wiry; the respiration exceedingly laborious; the countenance anxious, and of a leaden colour. He answered questions coherently, and chiefly complained of difficulty of breathing. On the following day he rallied a little; the sputa were still bloody, and mixed with mucus, but the blood had not appeared in large quantities. He remained nearly in the same state on Saturday and Sunday. On the latter day the patient called my attention to a pulsating movement of the veins in the back of the right hand, which I also observed, although less distinctly, in those of the left. This symptom was more remarkable after each expiration, when the veins became elevated, but a very evident quivering pulsation occurred also during inspiration. Neither of these movements was synchronous with the arterial

pulse. When the vein was pressed, the pulsation ceased below the part where it was employed, but continued in the portion of the vein nearest to the heart; the jugular veins were prominent, but no pulsation could be observed in them. Early on Monday morning the bleeding returned, and the patient almost instantly expired.

Sectio Cadaveris.—Monday evening. The right lung adhered firmly to the ribs, and could not be separated without laceration. It was thickly studded with tubercles. An excavation of about the size of a hazel-nut was discovered beneath the clavicle. The left lung was also bound to the ribs, but less firmly than the right. It was emphysematous, and was completely gorged with blood in a fluid state. No tubercles could be detected in it.

The heart was pale and flabby; the right auricle and ventricle were greatly dilated; the parietes of the latter were about their natural thickness. All the valves were healthy.

Remarks.—I was at first inclined to attribute the venous pulsation in this case to the diminution of the column of blood occurring simultaneously with disease of the right side of the heart, of the existence of which there was sufficient evidence; but upon further reflection, I think it more probable that it was occasioned by the sudden effusion into the left lung, causing an obstruction to the free transmission of the blood, the right lung having been greatly condensed from previous disease. I offer this opinion with much diffidence, as it is contrary to the theory of Laennec and other celebrated pathologists, who attribute venous pulsation to regurgitation of the blood.

I have been led to the above explanation of this remarkable symptom, from a consideration of the character of the pulsation, which was a gradual elevation of the vein following each expiration, but was not synchronous with the arterial pulse; and the absence of the stethoscopic signs, which indicate either regurgitation or valvular derangement, and also the remarkable condensation of both lungs, which the post-mortem examination disclosed. The fluttering irregular pulsations which occurred during inspiration were probably the result of the auricular contraction, and perfectly coincide with the observations of Dr. Hope on that subject.

SUPERSULPHATE AND SUPER-ACETATE OF IRON.

To the Editor of THE LANCET.

SIR,—I have sent you an account of the effects which have almost uniformly resulted in the undermentioned diseases, from the internal exhibition of the solutions of the supersulphate and superacetate of iron. I am, Sir, your obedient servant,

J. PELHAM BUCKLAND.

84, Watling-street, St. Paul's,
Oct. 13, 1835.

The colour of the solution of the supersulphate of iron is dark-brown; the taste is exceedingly rough; it dissolves sulphate of quinine, and is decomposed by the same preparations as the sulphate.

CASE 1.—I was consulted in April 1832, by a gentleman who had been subject for a considerable time to periodical returns of neuralgia faciei. He had been affected with the disease in a greater or less degree uninterruptedly for three months previously to his consulting me, and during the whole of that time had taken the subcarbonate of iron in large doses. The paroxysms had now become very severe, and at each intermission the part was left so excessively tender, that he was unable to bear the slightest touch.

I commenced my treatment by giving him ℞x of this solution three times a day, and a gentle aperient every second night. The paroxysms in a few days became less violent. The dose was then gradually increased to half a drachm three times a day. He was completely cured within a month.

The effects produced by the increased dose were, entire loss of appetite, and excessive dryness of the skin, which the patient described as being drawn too tight upon the body. The secretion of urine was very small, the heat of the skin rather diminished. These symptoms arising from the too large dose of the medicine, were entirely removed in a few days by the daily use of warm cathartics. Since this case I have never given it in larger doses than ten minims three times a day. Early last spring, this patient had a return of the complaint, when the liq. ferri supersulphatis was given in smaller doses with success, and without any unpleasant results.

CASE 2.—I have given this solution in several cases of leprosy, with most beneficial effects. In cases of long standing were completely cured, and in others were nearly so, the strength greatly increasing.

CASE 3.—Night perspirations arising from general debility are very soon checked by its use. In one case I gave it to a gentleman who had been taking sulphate of quinine with sulphuric acid for two months without any benefit. In about ten days from the time of his commencing to take this preparation the perspirations had entirely ceased. This was in 1833, and he has not since had any relapse.

CASE 4.—*Paruria Mellita*, a person residing in Wiltshire, who has had this complaint for two years, took during the first eighteen months, among other remedies, various preparations of iron, the sulphate, tincture of the muriate, ammoniated iron, but did not receive the slightest benefit from either of them; for the last six months, during which he has been my patient, he has taken this preparation in doses of ten minims three times a day. He felt great relief from it within the first month, and is now gaining strength and flesh every day, and losing the other symptoms of the disease.

Remarks.—The medicinal properties of the solution of the superacetate of iron are similar to those of the supersulphate. It is much pleasanter to the taste, and is readily taken by children when mixed with sirup and water. I give this preparation with much benefit in muc-enteric diseases. From one to three drops three times a day in sirup and water, is the dose which I generally prescribe for children of from one to three years of age. In weak chlorotic patients also, this medicine is of great utility. The dose for an adult is from five to ten minims two or three times a day.

Every practitioner is aware of the numerous complaints in which iron may be exhibited with advantage. In all of them which have as yet fallen under my care, I have found these preparations to agree better with the patient, and occasion less nausea, than those generally used; I therefore have not considered it necessary to occupy more space in particularizing their effects in other instances, the above being quite sufficient to afford a general idea of their properties.

AN HERRIVOROUS MAN.—Anthony Julian, a native of Var, fell suddenly into such poverty during his youth, that he was compelled to eat plants. That which was at first painful food soon became an object of choice; and although in a few months his constitution was altered, he continued to live on this vegetable diet with the exception of a little bread, which he could not do without. The digestion was perfect, and his health increased in an extraordinary manner. *de Sc. and Arts of Varr.*

System der Chirurgie von Ph. Fr. von Walther der Philosophie, Medicin, und Chirurgie Doctor &c. &c. (A System of Surgery) by BARN WALTHER, 1 vol. Berlin, 1833. Reimer, pp. 418. (Imported by Schloss.)

WALTHER is one of the truly great surgeons who do honour to his father land, and his works on Physiology and several detached papers on Practical Surgery in the Journal published by Graefe and himself, have greatly contributed to the progress of the higher order of medical science in the northern states of Germany. To his lectures, he himself, however, attaches more importance than to his writings; they have been delivered regularly ever since 1802, and, enriched with improvements supplied by the entire range of medical literature, and by many years of meditation and experience they have arrived at a state of high maturity. At the medico-chirurgical school of Bamberg, the University of Landshut, Bonn, and Munich, he speaks with a becoming pride now, in his riper years, of having had for auditors many of the most distinguished German surgeons of the present day.

The volume before us is the first of a series intended to present the whole of his course and system of surgery. It develops the *general principles* of surgery, and constitutes that to the succeeding volumes, which general does to particular or topographical anatomy. The Professor has, from the first step in his professional career, followed the leading ideas that medicine not only reposes on natural philosophy, but that it is itself *natural philosophy*. This position being firmly embraced, he cannot admit that its practice as an art, or its utility to society, admits of its division. In every point of view, Walther's System of Surgery merits that name better than any other extant. Those who prefer natural grouping to the A B C arrangement, or who, like Gibbon, "can never digest the alphabetical order," will find in this logical and purely rational system, many charms, and some consolation, for the present form of medical writing which prevails in England.

The forms of disease treated in surgery are divided by the Professor into five classes. To the first belongs INFLAMMATION, its terminations and sequelæ (*phlogosen*); to the 2nd, WOUNDS, solutions of continuity (*traumen*); to the 3rd, DISPLACEMENTS OF

organs, changes of configu (ectopieen); to the 4th, MALFORMATIONS, producing destruction of function and deformity (*pseudomorphen*); to the 5th, FOREIGN BODIES, penetrating from without or generated within (*allenthesen*).

In the first chapter, that on inflammation, the adaptation of the treatment to the different forms of malady, is strikingly felicitous. The modifications of treatment, according to the character of the inflammation, where the habit of body is catarrhal, rheumatic, scrofulous, syphilitic, arthritic, or scorbutic, and according to the tissues or systems suffering, will be best appreciated by those who have had most experience in practice, and have seen on what slight causes success or failure depends. The indications for bloodletting in inflammation are thus stated:—

“Venesection is indicated with an urgency proportional to the intensity of the inflammation, the importance and vascularity of the organ, the danger of entire destruction or breaking up of its function,—to the phlegmonous character of the inflammation, the earliness and activity of the stage, the acuteness and tendency to spreading, the freedom from any dyscratic combination,—to the violence of the accompanying fever, the strength of the constitution, the richness of blood, the habits of the patient with regard to loss of blood.

“Redness of the face, the fulness, strength, and hardness of an incompressible pulse, high-coloured urine, dryness and heat of the skin, are indeed subordinate, but confirmative of the indications. Chronic inflammation frequently requires bloodletting, also dyscratic (scrofulous &c.) inflammation, if it assumes a dangerous appearance; only, in these cases, blood-letting cannot do all that is required; it can only cut short one element (the inflammatory) of the disease; the other (the dyscratic) element is not by that means arrested, but rather furthered in its development.

“Erysipelas, also, particularly of the face, bears and requires bleeding, keeping at the same time in view the origin and character of the fever, and the complications and likelihood of its return.”

Also in children a little advanced in age, venesection is necessary in dangerous inflammation. Menstruation, the lochial discharge, hemorrhoids, are by no means invariable counter-indications.

Suppuration and the other terminations and kinds of inflammation are afterwards examined in the most comprehensive manner. Wounds are defined as violent se-

parations of the cohesion of organic structures. They are examined according to their form, and the part or tissue injured,—in the skin, the muscles and tendons, vessels, nerves, and bones (fractures). Cuts, stabs, bruises, lacerations, gun-shot wounds, poisoned wounds, inoculated wounds (chancres, hydrophobic wounds, &c.), are treated in successive chapters.

General and ingenious ideas are occasionally met with like the following, in the first chapter of the class of “displacements,” the value of which will not be fully appreciated by every reader:—

“The organs of the human body are fixed in certain predestined localities. They can neither be developed, nourished, nor grow, and rightly fulfil their functions, unless they are placed in that precise local relation on which their insertion in the vascular and nervous systems, and their relation to the neighbouring organs,—by which they are supported in their functions,—in great part depend. As families of plants are confined in their geographical distribution to particular zones, to various degrees of latitude and longitude, to a definite elevation above the level of the sea, to certain climates, so is there for the organs of the human body a topical arrangement and normal position. Therefore, viewed in their totality, similar organs in the different classes of animals, always live in the same or corresponding places, and every displacement is also a correlative loss of dignity and destination for the dislodged organ.”

Intussusception, hernia, prolapsus uteri, dislocation, paraphimosis, belong to this class.

Malformations of every kind, harelip, cleft palate, imperforations, strictures, ectasies, aneurysms, varices, aneurysms by anastomosis (*telangiectasie*), curvatures, and club-foot, form, in separate chapters, the fourth division (*pseudomorphen*).

Further remarks on this work are unnecessary. The reader must have seen sufficient to enable him to understand the author's arrangement. Without extracting more than our limits will admit, it would be impossible to give a just notion of its intrinsic value. For condensation of philosophical reasoning, and combination of surgical science, and clarity of view, it surpasses any work lately published.

On the Power, Wisdom, and Goodness of God, as manifested in the Creation of Animals, and in their History, Habits, and Instincts.
By the Rev. WILLIAM KIRBY, M.A., F.R.S., &c. Vols. 1 and 2. London, Pickering, 1835. 8vo.

THE author commences his work by remarks on the opinions of the two well-known French philosophers, La Place and Lamarck, but more especially on those of the latter, as being pre-eminently the works of naturalists. Although we cannot agree with many of the ideas started by the latter in his "Philosophical Zoology," we nevertheless think they deserve the consideration of inquirers after truth. His main hypothesis of the gradual conversion of the lower into the higher order of organized beings, by the influence of external circumstances, assisted by "the lapse of ages," is not satisfactorily made out. He has certainly produced a few facts to show, that when an organ is not used, its power gradually declines until it may be said *not to exist*; and, *vice versa*, that when it is much used, what may be called its "natural" state is rendered more perfect. This is matter of common observation, and has been long known. Lamarck, however, has considered it more particularly than have the generality of physiologists; and although he has made some ingenious deductions from it, and some that are correct, we still think that every impartial man who has attended to the subject, will so far agree with Mr. Kirby as to perceive, that the French philosopher has by no means yet brought forward a sufficient number of facts to establish his main hypothesis. Lamarck perceiving that change of circumstances, assisted by time, will to a certainty produce *some* variety in the animal species, has conceived, that such change of circumstances, aided by an *incalculable extent of time*, may have produced *all* the varieties which we see in the organized world. The hypothesis is plausible at first sight, because it is not altogether unsupported by facts; but when examined more closely, it is obvious that by far the greater part of it, though not altogether "irrational," as Mr. Kirby calls it (page 24), has *no* foundation in observation, experiment, or reasoning, so that at best it can only be regarded as the flight of a hare's post. Leaving this point of the subject, no assurance may be called to the

fact, that Meckel* has shown that our life in the womb first resembles the life of an egg or an animalcule, and next that of a fish or a cold-blooded animal, which has *only a single heart*, till at length, as the time approaches for our appearance in the open light of day, our vitality assumes the character of the warm-blooded species, and we appear in the world with a *double heart*. Considering these facts, Meckel supposes that he perceives something like a tendency of matter to rise from the lower to the higher forms of existence. We do not think he has added (as he might have done), that not until long after birth does the child acquire what may be called the "true prerogative" of its species,—reason. This,—not exactly, as some have said, "built up from the external senses,"—is still something superadded or developed *after* the animal has risen to the top of the organic scale, and become warm-blooded. Animalcule, reptile, dog, its master. Such seems the ascending series.

Sir Charles Bell, in his "Bridgewater Treatise," is opposed to these ideas of Lamarck and Meckel. He considers the lowest animals to be as perfect in themselves as the highest. This is an argument that deserves consideration from those who engage in these difficult inquiries. The ant and the bear, and indeed some *reptiles*, such as the crocodile, seem often to have given proofs of sagacity which should make us hesitate whether it is right to consider those animals which will lie low in Lamarck's and Meckel's series, as so ranging in reality. The world is *one* vast piece of mechanism (some may say), every part of which is so arranged, as to fulfil the intentions of the incomprehensible Artificer; and it is absurd to consider one part to be higher or lower, more perfect or less perfect, than another. With regard to Meckel's above-stated observation, it seems to be the sole instance that we at present have of life beginning at what we call the "bottom" of the scale, and gradually ascending to the top. Conceiving it to apply not only to the human species, but to all the warm blooded species, it is still to be remembered that this all takes place *in* the body of the parent, and *not out of it*. There is, properly, at present, so far as we know, not a single example of such a tendency of

* "Anatomy."

matter as that which is supposed by Lamarck and Meckel, existing out of the parent animal.* Tiedemann, indeed, in his late work on physiology, supposes that our body after death becomes gradually changed, as decomposition advances, into myriads of animalcules, which again pass into vegetable and thence into animal forms of existence. And this may be the fact, so far as that animalcules are produced by decomposition, and that these, by their death, or, possibly, by their life, may contribute, rising among the vegetable juices, to the vegetation of the seed, by affording it nutrition, or *stimulating* it, assisted by air and water, to action. But it is not the fact (so far as we at present know), that each animalcule is *changed* into the seed, or even into a part of the seed. Much less is it a fact, that the lower orders of vegetables are changed into the higher, or into any form of animal life. True it is, that the vegetable, when dead, may,—as it were, after another death,—after chemical *decomposition* by the animal fluids,—become changed into a part of the animal again alive. But this is a very different thing from a vegetable actually growing into (changing into) an animal; or an animal of the lowest species changing into an animal belonging to a higher class in what is called the scale of organization.

Again, if it be said,—“But animalcules, which are *living* matter, are obviously produced from the fermentation of animal or vegetable infusions which are *dead* matter, and hence display the existence of a disposition in matter to rise from death to life,—from a lower to a higher state of being,”—we may reply, “That has been questioned.” Spallanzani conceived the *eggs* of the animalcules to float about in the air and elsewhere, and only to be hatched (so to speak) when they accidentally fell into a proper nidus. Such he conceived decomposing infusions to be. Knowing that some of the animalcules may themselves be kept for many years (as the wheeler for instance), and yet show signs of life on being moistened, it seems by no means impossible that

the eggs of those animalcules may float about in a dry state in the air, perhaps for hundreds of years,* and yet not lose the power of becoming living animalcules, should they chance to fall into an infusion suitable to produce such change. This seems to be the less improbable, because these animalcules often propagate by division, like vegetables, and the seeds of which we know may be kept dry without injury for years. Lamarck, however, and some other naturalists, seem inclined rather to believe that animalcules are actually *generated* by decomposition. But there is strong analogy against such a supposition. We have proof that no other insects or animals are so generated. At least such a phenomenon has never yet been discovered in others.

It seems, therefore, to follow from what has been said, that when the visible animals originated, some cause was in operation which is not in operation now; and the same may be said of the transmutation of the lower into the higher forms of existence, if, indeed, this was the order of creation.

We select the following observation with regard to life from Mr. Kirby's Treatise. It affords a specimen of the original views which are frequently to be met with in the work.

“Thus much, however, may be predicated of life, that both in the vegetable and animal, like heat, it is a *radiant* principle, showing itself by successive developments for a limited period, varying according to the species, when it begins to decline, and finally is extinguished: that sometimes also like heat, as in the seed of the vegetable and egg of the animal, it is latent, not manifesting itself by development, till it is submitted to the action of imponderable fluids conveyed by moisture or incubation.” —p. 40.

The reverend author thinks that the hypothesis of Mr. Mantell, viz., that the saurians were the mighty masters of the creation before the existence of the human race, is not altogether satisfactorily made out. “The supposed extinct animals all exhibit a relationship to those that we find now existing and many of them evidently fill up the vacant spaces in the general system, and therefore there is no cause to suppose they were originally separated from the present race.”

* Nor does there exist evidence that such a tendency has ever existed. “There are no fossil remains in the lower strata of the earth, of vegetables and animals, of oaks and lions, in miniature; or of creatures with organs half formed; while in the upper strata they are found in a state of greater perfection.” See “Allan's Discourses against Atheism,” Discourse 4, p. 186. This work was not known to us until after the present article was written.

* It is not necessary to suppose that they floated from their first origin, but that they possibly be borne up into the air, being left behind after their infusile may be carried up by the wind.

to their fellows." We do not, however, observe any new or striking arguments brought forward in favour of the notion that extinct animals were created at the same time as those which are at present in existence.

In chapter II. a great many ingenious arguments are advanced to show that America may have been stocked with men and animals from the old continents. Land connexions, subsequently swallowed up by the sea, "floating islands of matted wood," similar to those observed by Captain W. H. Smith &c., are urged as possible modes of transmission. The author, in the Appendix to the first volume, and elsewhere, has endeavoured particularly to make geological researches accord with the Mosaic account of the deluge. In aiming at this as a *general* principle, he is doubtless serving the cause of Scripture; but in urging the existence of coincidences to such an extent as he has attempted to carry them, we doubt much whether he has not overshot his object. This error the traveller committed who, in proof of the transmutation of Lot's wife into salt, announced that he had found the pillar in the desert. The expression relative to the sun standing still, and others of a similar description, show, that however plausibly we may interpret to the letter some parts of the most ancient records, we cannot do so in all. And if we cannot do so in all, to labour at parts shows our anxiety to be more prominent than our wisdom, for partial success must lead to rejections which the interpreters will not desire.

We leave the perplexing subject to make some remarks on the chapter "On Instinct." "An ingenious and acute writer, Mr. French (says the author), is the author of the hypothesis that instinct is the action of some *intermediate* intelligence employed by the Deity upon the animal exhibiting it,—an hypothesis (continues our author) which appeared in the first number of the *Zoological Journal*." It seems by another quotation, that Mr. French conceives "these intermediate intelligences to be *good* and *evil*, but acting under the control of Providence; and that such agencies act by impressions upon the conscious nature, but unperceived by the moral or intellectual faculties." The author remarks on this in common phraseology, "that these intelligences would be

called "*Angels and Demons*," the former being the cause of the *beneficent*, the latter of the ferocious instincts of animals. "It is further obvious, (he continues,) that Mr. French believes that the *same* animal is subject to the agency of *both* these powers; since, he has observed that in the phoca ursina species, the males manifest the most singular tenderness towards their young progeny, and at the same time a savage and persecuting disposition towards their females."—p. 233.

Mr. French might have gone farther, and said that as an attraction to the centre and a tendency to motion (the centripetal and centrifugal forces) seem to pervade all inanimate matter,* in like manner two opposing powers, benevolence and malevolence, selfishness and generosity, seem, though in different proportions, to pervade all organized animal matter. We say in "different proportions," for it is obvious that in some animals (man included) the benevolent principle is the stronger, in others the malevolent. Were we called upon to make two grand distinctions on this subject, we should say that herbivorous animals were inspired more particularly by the benevolent powers, and carnivorous by the malevolent; at the same time admitting that even the herbivorous are sometimes actuated by the malevolent influence, and the carnivorous by the benevolent.† There is little that is new in this opinion. Plutarch says, in his Essay on Isis and Osiris, that it was entertained by Zoroaster and the Egyptians. It was the opinion of Plutarch himself—if not in its details, at all events in its outline. It was the opinion of Bayle. Further, it is an opinion that prevails more or less among all educated nations even of the present day. The "Devil" we are told entered the serpent "in the beginning," and the serpent has since retained venomous and malignant qualities.

But the reverend author does not coincide with Mr. French in his opinions on in-

* Mr. Kirby has a remark somewhat similar to this as regards instinct and intelligence, which latter is considered a "principle of limitation."—P. 27, vol. 2.

† Having no space for details, we have said nothing about fair, necessity, or the obstinacy (or opposing power) of matter, suggestions of Plato; yet does Paley *indirectly*, in accordance with scriptural doctrine, admit the agency of one at least of these. We do the same, and in this way show how the benevolent is stronger than the antagonist power.

Not so the rose. The queen of flowers is perhaps the most accomplished of chemists, during life converting corruption into sweetness, and retaining comeliness and wholesomeness even after death, falling slowly only into inoffensive dust. The queens of birds and of humanity perish into odiousness.

Quaint enough is the following erection on scriptural theory:—

"It is singular that two classes should be placed in opposition to each other, seemingly so opposite in their character and most of their qualities, as the reptiles and birds—the one the most torpid, dolful, and hateful of animals, symbols of evil demons,—the other *vice versa*.

But in spite of this apparently striking contrast, a real affinity exists between birds and reptiles (in their general form &c. &c. of course is meant, each too being oviparous); and when we recollect that demons are fallen angels, we may apprehend why God has placed their symbols in the same series." (Page 441, vol. 2.)

To conclude. Though we differ from the author in some of his opinions, yet we acknowledge the work to be one of merit, and calculated to afford considerable pleasure in the perusal, to thoughtful readers. Many of the observations which it contains are at once original and judicious, and if the pursuit of truth does not always satisfy the reader by its success, the path at least affords food for meditation. The materials for thought are certainly supplied in his pages, which can rarely be said of "new books" in this age of literary vampation; and in casting yet further abroad a little of the seed which he has therein sowed, we shall probably cause some to alight in a soil that will afford it growth which it would not otherwise obtain.

The Principles of Ophthalmic Surgery; being an Introduction to a Knowledge of the Structure, Functions, and Diseases of the Eye; embracing new views of the Physiology of the Organ of Vision By JOHN WALKER, Surgeon to the Manchester Eye Institution. London: Taylor, 1834. pp. 195.

THE title of Mr. Walker's work is sufficiently explanatory of its nature. The structure and diseases of the eyelids, of the eyeball, the cornea, the iris, the ciliary apparatus, the choroid, the retina, the vitreous body, the posterior chamber, the anterior chamber, the lacrimal gland, and

the passages are successively and succinctly discussed. A vocabulary is added, explanatory of technical terms, with the German and French synonyms. This is exceedingly useful, nay, indispensable to the student, who will readily admit the fact when he finds that there are more than one hundred distinct diseases of the eye, each characterized by some hieroglyphic forged out of Greek, by the laborious wit or the dullness of the Germans. Three hundred technical terms are already employed by the ophthalmologists. In the name of common sense, and on behalf of the verbal memory of their brethren, we now entreat them to desist from further neological creations, which, instead of diffusing light, threaten us with the perplexities of chaos again. Let our translators resolutely resist the German verbiage. None sooner than ourselves are willing to acknowledge German genius whenever it appears; but we caution our countrymen against giving currency to the piles of incubrations which are retailed at the Leipsic fairs. A German Professor is an author, often a nonnomenclaturist, *ex officio*; and the dense stupidity of a German duncer surpasses any thing of the kind in nature.

The examination of the physiology of the iris, in which Mr. Walker comes to conclusions differing from those generally held, will afford a favourable specimen of his method of reasoning in physiology.

"It has been usual to refer the motions of the iris to a supposed connexion with, or dependence upon, the retina. Many facts may be advanced in proof, that the changes of the pupil are independent of the retina. They have no communication with each other—their nervous supply is totally different, the sensibility and mobility of the iris depending upon the ciliary nerves;—the retina communicates only with the optic nerve. In many cases of paralysis of the retina, the iris is perfectly active. The opposite condition is also frequently noticed of dilated and motionless pupil, without loss of vision. Either of these conditions is perfectly irreconcilable with the idea of the motions of the iris being dependent upon the retina: both form such an insurmountable objection, that they cannot be got over.

"In the most densely opaque cataract, where very little or no light can get to the posterior chamber, the pupil, instead of being proportionally dilated to the unexcited state of the retina, is as active and as much contracted as ever, which could hardly be the case if that activity depend upon the quantity of light sent to the retina.

"To explain this more clearly, we will

adduce two instances, in which the facts will speak for themselves. 1. A.B. is affected with cataract of both eyes. The lenses are so opaque, as to allow of scarcely any light getting to the retina, consequently he is unable to discern any object but very indistinctly. *His pupils will be as much contracted as those of any other person.* 2. C.D. has no cataract. His vision is perfect. He is placed in a darkened room, where there is so little light to affect the retina, that he is unable to discern any object but very indistinctly. *His pupils will be widely dilated.* In these instances the retina is similarly situated as to the stimulus of light; and yet we find the pupil dilated in the one case, and contracted in the other. The inference to be drawn from these facts is, that the exterior of the eye and iris are acted on by the light, and that the contraction of the pupil is the result of that action; and, consequently, that the latter is not influenced by the quantity of light sent to the retina.

"In the state of sleep the pupil is powerfully contracted, whilst the retina is unemployed, and in a state of complete repose.

"By means of the lenticular ganglion, which gives off the ciliary nerves, the iris is connected with the palpebræ, by the third and fifth pairs of nerves; and all its relations seem to be with the eyelids and not with the retina. It is very common to find them both simultaneously affected with disease:—thus, if there be paralysis of the third nerves, the levator palpebræ and the iris are both motionless. In the experiments of Magendie, when the fifth nerve was divided, in dogs and cats, in whom the arrangement of these nerves is the same as in man, the iris was paralyzed, and the eyelids could not be closed. I have seen disease, in which the eyelids and iris were both in a state of continued spasmodic action, a constant twitching and closure of the eyelids, and a corresponding rapid contraction and partial dilatation of the pupil, owing apparently to irritation affecting the fifth pair of nerves. Instances of this affection cannot be considered as by any means uncommon, since it is particularly noticed by Beer, to whom it could therefore be nowise strange.

"By reference to the facts of comparative anatomy, this view of the relation between the palpebræ and iris is strengthened and confirmed. Insects are devoid of either. In fish we find the iris perfectly formed (as a portion of the optical apparatus), but motionless and no eyelids. In the amphibia the iris is also present, with a feeble languid motion; and here we have the first rudiments of eyelids; these consist of folds of the common integument, with which the animal occasionally covers the eye, placed anteriorly and posteriorly, and resembling the third eyelid of birds and the mammalia. In birds the eyelids are perfectly developed, and the iris exceedingly active. Keiser

found that after cutting away the eyelids in birds, the contraction of the pupil accompanied every fruitless attempt to close the lids; so that it would appear that the motions of the iris are voluntary in them. Carus, from whose 'Comparative Anatomy' these facts are taken, asks, 'Does not this consonance of motion in the eyelids and iris, as well as the development of mobility in the latter at the same time with the first appearance of eyelids, go far towards proving its muscularity?' It may be taken equally as a proof of their mutual action and relation.

"In the mammalia we find the same striking analogy between the eyelids and iris. Before birth, as in man, the pupil is sealed up with the papillary membrane, and the eyelids are closed by a similar membrane; and in those animals which are blind at birth, both these membranes disappear together.

"From all these remarkable and striking agreements, it is not too much to draw the inference I have done, viz., that the sympathies and relations of the iris are with the palpebræ and not with the retina. I challenge the advocates of the latter opinion to bring forward such a string of facts in support of that view."

We recommend Mr. Walker's book as a very meritorious performance; every subject which he has discussed is treated clearly and with good sense.

An Introduction to Hospital Practice in Various Complaints: being a Clinical Report of Fever, Gout, Rheumatism, Cholera, Jaundice, Erysipelas, Insanity, &c., and Diseases of the Chest and Heart, with Remarks on their Pathology and Treatment. By C. J. B. ALDIS, M.A., M.B., and L.M., Inceptor Candidate of the Royal College of Physicians. London: Longman, 1835. 8vo, pp. 125.

PERIODICAL medical literature can render no much greater service to medicine than must result from the publication of carefully-observed and well-digested reports of hospital cases. Physicians and surgeons in large private practice can only present us with general conclusions, leaving us, too often, in ignorance of the facts and observations upon which those conclusions have been founded. It is for advanced students or young physicians, who cannot spend some hours daily in the hospital, to collect the facts which occur from the superintending care of

to lay before the public a full account of "the evidence," of which the more experienced practitioner can only report to us the "summing-up." In the hospitals the medical officers should themselves set the juniors to work, and arrange and complete the materials collected, the independence and honesty of the collectors being the guarantees for the fidelity of the reports. If they will be at no pains to perfect the documents produced, at least should they afford every facility to enable others to perfect them. However, there seems to be so much reason for the preservation of secrecy in British hospital practice, that there is no hindrance or obstacle which, with few exceptions, is not thrown in the way of reporting cases honestly and impartially, in the national medical charities of this country. In France, a greater compliment cannot be shown to an hospital medical functionary, however high and eminent his reputation, than to report his cases in the public journals.

There are sometimes, however, followers in the wards of our hospitals on whom the physicians and surgeons can depend,—as a lord can depend upon his amanuensis, or a prince upon his little foot-page; and now and then we have these *attachés* issuing reports or brochures of cases, "selected," judiciously selected, and fitted for publication, with the grand name of the hospital affixed to the title, and an equally grand name in the dedication. Yet such publications must contain much that is veritable, and ought, imperfect though they may be, to present us with much that is valuable.

Dr. C. J. B. Aldis is neither a foot-page nor an amanuensis. He is an M.A., an M.B., an L.M., an I.C.O.I.R.C.O.P.L. and a D. to his M. E. M. K. W. the 4th, P. and P. to St. George's H., and of all N.I.'s,—which latter series of initials being interpreted, means that Dr. Aldis is a Dedicator "to his Most Excellent Majesty King William the Fourth, Patron and President of St. George's Hospital, and of all noble Institutions.—What a simple thing is science! What grandiloquent personages are some of those gentlemen who follow in its wake! We will frequently furnish our readers with a specimen of these "selected cases" which Dr. Aldis has so kindly placed at our disposal to "the patient and the public." His present publication has certainly induced us to consider whether we may have enter-

tained of engaging him as a reporter at St. George's, notwithstanding the fact that he has been there for a "series of years" learning the occupation. Suppose his most gracious Majesty had met with the following case in our columns, which position it has missed, occupying, instead, a place in page 32 of the "Introduction to Hospital Practice,"—a work which is designed "to prevent numerous valuable facts from sinking into oblivion."

"Case of Infantile Remittent Fever.

"Charles Wellington, æt. 3½, admitted December 7, 1831. Pulse 120; skin warm and moist; bowels open and motions dark; urine clear; abdomen rather swelled; emaciated; voracious appetite; coughs and expectorates thick phlegm.

"Had the measles three months ago, which were of an irregular character, and he has not been well since.

"R. Hydrag. Submur. gr. ij;

Pulv. Jacobi gr. j. o. n.

Haust. Sennæ ʒss, omni mane.

Haustus Celacei ʒss, sextis horis.

Diatla Lactea.

"9. Prolapsus ani.

"Enema Aquæ Frigidæ ʒij, quotidie, P.

"14. P.

"25. The prolapsus ani has ceased; the injection has consequently been omitted; no cough.

"P. c. Hyd. Submur. et Jalap. alt. nocte.

Haust. Sennæ posteris diebus mane.

"Jan. 2, 1832. Cured."

This is *verbatim*. It constitutes case 17. Does Mr. Aldis seriously present it either to King William or the profession as an hospital report; or does he think himself privileged, as an inceptor candidate, to publish what the merest tyro in the profession, who possessed the same opportunities for observation in the hospital, would be ashamed to own? Look at the previous history of the case—"measles of an irregular kind three months ago." How precise! "Has not been well since." How clear a description of the premonitory symptoms and previous state of health!

The report of the 14th day is unique in medical records: "14th.—P." Probably Mr. Aldis shook his learned head as he wrote the algebraic fact of "P." A shake of the head stood for much with a *dramatis persona* in the "Critic," and may have been equally expressive *here*. But then we do not see it. Perhaps the printer, to whom the notice of

the significant movement of the head was new in "composition," omitted "a shake of the head" after "P.", in ignorance. At any rate it would prove profitable penny-a-line work to Dr. Aldis, to obtain a "P." engagement on the periodicals.

The greater part of the cases reported are very nearly of the same description. Thus the entire subject of *croup*, which the author describes as "cynanche trachealis," is dismissed in a single case, which occupies three-fourths of a page, while the sum of information on the spasmodic form is contained in the following extract, which embraces every word contained in the article under that head.

"*Spasmodic Croup*.—This is opposed to the former, which may be termed inflammatory croup. It usually attacks patients suddenly in the night-time, and is unaccompanied by the symptoms of pyrexia, which commonly distinguish the former. There is often an intermission of the disease. The warm-bath and antispasmodics compose the treatment."

We have seen, within the last few years, several works, British and foreign, on diseases of the heart. We beg the authors of those works to consider how absurd have been their labours, when they learn that Mr. Aldis has discovered that the diseases of the heart consist simply of hypertrophy and ossification, and that we could print every word which he has to say on the subject of the former in one page of our journal, the latter being concentrated in the following three lines, immediately after dismissing the cases of hypertrophy.

"The remaining diseases of the heart consist in ossifications, which may be palliated by medicine and repose, and life may be prolonged by avoiding excitement."

And it is to give encouragement to such piddlers in cases as Dr. Aldis, that our hospital doors are almost closed against the reporters for the public press!

Practical Observations on the Nature and Treatment of Nervous Diseases, with Remarks on the Efficacy of Strychnine in the more Obstinate Cases. By GEORGE RUSSELL MART, M.R.C.S. L. London. Churchill. 1835. pp. 185.

THIRTY-TWO more miracles performed by strychnine! Mr. Mart has come from H.M. Ship *Racoon* to the assistance of Dr. Turnbull, and discharged a very destructive

ambrosia against hemiplegia, paraplegia, amaurosis, nervous indigestion, the douloureux, and neuralgia. Like the production of Dr. A. B. and C. D. Turnbull, the present work is not,—Oh, fellow countrymen!—a list of the killed and wounded. It resembles, more, a Report of the Humane Society, and contains only a catalogue of the saved. The victims who used to escape from shipwreck offered gifts to Neptune, and the temple of the Ocean God contained many proud trophies of his power, which the priests exhibited with immoderate elation to the devout stranger: "Where are the memorials of those who perished?" was a question which overwhelmed them with amazement." We ask Mr. Mart, and we shall continue to ask all the proclaimers of new medicines—"To how many patients did you administer your drug without producing the least advantage from its employment?"

The author of the work on strychnine has "for many years successfully administered strychnine in paralytic complaints, as the relation of some very obstinate cases will prove." These cases are very clearly, and we have no doubt very fairly, related. The work is, indeed, one of the best yet published on strychnine, and goes as far to verify its efficacy as can any book which relates to successful cases only, and does not pretend to ascertain their duration. The following extract affords a favourable specimen of Mr. Mart's cases:—

"*Case 7.*—Thomas Linton, aged 42, had been two years in the *Racoon Hospital*, in Portsmouth Harbour, before the date of the author's appointment thereto. He was tall, thin, and had a sallow complexion, and was the most intelligent patient in the ward. He stated that he had not quitted his bed for twenty months, except on favourable days, when he was carried on deck for fresh air. The cause of the palsy was a blow on the loins by a fragment of stone, attended with considerable pain at the time, which in a day or two passed off. Sometime afterwards he became alarmed by a feeling of numbness extending along the thigh, and a sensation as though strings were tightly bound round the legs. These symptoms increased, and at the end of three weeks the man was deprived of motion of the legs, and became unable to stand. Every cure was tried, in vain. At length, however, the poor Linton received strychnine, and was considered 'an incurable case.' The treatment was continued for some time, and the patient recovered."

ministering some blue pill, and doses of purgative medicines; the state of the secretions required previous treatment. Afterwards, one-eighth of a grain of strychnine was ordered in the form of a pill twice a day, and a dose of a mixture containing diluted sulphuric acid taken at the same time. On the second day the pill was repeated three times, and the strychnine was gradually increased to a grain in twenty-four hours. When the treatment had been continued a month, no amendment occurred; but about this time a blister was applied over the part where the blow was received. On removal of the skin, one quarter of a grain of strychnine was applied twice a day. The blister was dressed daily in this manner till it healed, when another was applied in the vicinity, which was dressed with half a grain of strychnine sprinkled over the denuded surface twice a day, and also administered internally in pills containing a quarter of a grain four times a day. Six weeks from the commencement, the patient began to improve; convulsive jerks were felt in the legs, and a sense of pricking and other odd sensations were experienced; the toes would move involuntarily. An erect posture had been attained several days; the patient sat in a chair, and moved the legs in every direction. He continued to improve in various degrees, but the amendment was always more rapid after blistering. This treatment was continued four months, when he was so far recovered as to be discharged from the Hospital Ship, and had light work assigned him. Finally the cure became perfect, and he performed the duties of an able-bodied man."

Practical Anatomy of the Nerves and Vessels supplying the Head, Neck, and Chest, &c.—

By EDWARD COCK, Demonstrator of Anatomy at Guy's Hospital.—London. 1835. Schloss. pp. 249.

THE preface to this little work contains an apology from the author for adding one more to the long list of existing "manuals" of anatomy. The excuse, however, is unnecessary. The work is well executed, and we especially approve the plan on which the anatomical researches in the regions displayed is conducted.

There is no occasion for us to enter into a public examination of the contents of the volume, or to analyze its details, which are purely anatomical. Mr. Cock does not pretend to have made any discoveries; he directs attention for the manner in which the vascular and nervous system of the head, neck, and the thorax, and the mod which we have always

considered to be the only one that is really calculated to aid the student in his inquiries in the dissecting-room. Instead of commencing with the large trunks of the arteries and nerves, the author takes them up (at the point where dissectors must commence) at their terminal branches, and then follows them to the more deep-seated parts, and intersperses his descriptions with a variety of remarks and directions for dissection, which none but a practical anatomist could have given, and which will render the greatest assistance to the student while he pursues this difficult portion of anatomy, scalpel in hand. In short, the author makes his work say that which the demonstrator would describe *viva voce*, with the parts before him, and in the same order as that in which the parts present themselves under the knife; and this handy volume may be conscientiously recommended to all those who desire to lay that sound foundation for medical knowledge which can be derived only from a practical acquaintance with the structure and relation of the parts composing the human body. The work is issued with the usual extreme neatness of Mr. Schloss, whom we may take this opportunity of recommending to students as the publisher of some excellent and valuable plates of anatomy by Weber, especially his Anatomical Atlas.

THE LANCET.

London, Saturday, October 17, 1835.

THE remarks which we have recently offered to the profession and the public, on the fraudulent lecture and certificate system, have produced, it appears, the desired effect on some of the most guilty of the delinquent parties. There is no trusting them to discuss this question, except in favour of one side. As all the arguments, therefore, are with us; all the calumnies, all the falsehood, or, to speak plainly, all the lies, are to be found in the columns of our opponents. It is pretended by our voracious adversaries that we advocate the apprenticeship system, and that we contend for the proposition of totally abolishing the practice of lec-

being in public and private medical schools;—that, therefore, we have argued that every surgeon should be so well capable of supplying his pupil with a competent knowledge of every branch of medical science, and that the pupil should derive no other instruction with respect to instruction in medicine, than that which can be furnished to him by the gentleman to whom he is articulated as an apprentice.

It is not in our power to present any specimen to our readers as a *refined* mode of lying, because nothing more gross, more truly gross, in the shape of falsehood, was ever presented to the observation of intelligent men. What we have been seeking to establish—and this is as well known to our shallow-pated opponents as it is to the profession—is a system of education in medicine, which has its foundation in principles of justice,—a system which will necessarily confer on all practitioners of medicine, the privilege, *when they are competent*, of supplying their apprentices or pupils with a competent knowledge of the theory or practice of the science of medicine. Hence, on a variety of occasions, we have felt it to be our bounden duty, in justice to the public, and in justice, too, to surgeons who are engaged in private practice, to expose the enormous abuses which arise out of the certificate system, enforced and sanctioned as it is by the rulers of our colleges and companies.

But the exposure, it seems, is a source of grievous annoyance to certain of our empty-headed lecturers. We are glad of it. We had no desire to please them, and quite certain are we that, if our criticism on that subject had been consulatory to *their* feelings, a better proof could not be furnished that we had sacrificed the interests of the profession. When, therefore, our opponents are most liberal in giving utterance to vituperations and falsehoods, we derive the greatest share of satisfaction; for of what use is it to apply the lash, unless we can make the galled jades wince? The adversaries of a just and rational system of medical educa-

tion, know well enough that THE LANCET has ever been opposed to a compulsory system of instruction of any kind, other than what is demanded by the capacity of the pupil to undergo a searching public examination. To this extent our advocacy of restriction has reached. Beyond it we have not gone a single step. The system of compulsory apprenticeship, instead of being landed in this journal, has been denounced by us, as well also as has the disgusting humbug of "recognised" courses of "four months" and of "six months" duration. It has ever been the object of our labours to set both practitioners and students free from such odious and pernicious trammels, as far as may be necessary to suit the interests and conditions of persons against whom the "recognised" system may operate—if not as an institution of extortion, at any rate as a provision which must be attended with great disadvantage. By the Apothecaries' Act of 1815—a measure which has called forth so many pages of eulogium from the pen of the hired hack of the corruptionist—the student in medicine who desires to practise as an apothecary in England and Wales, must serve an apprenticeship to an apothecary for a period of "not less than five years." When, however, this self-same student makes his appearance in the metropolis, with the avowed object of obtaining his license at Apothecaries' Hall, he is required to commence his studies *de novo*, and certain rules are prescribed for his adoption, a compliance with the terms of which requires a residence of nearly three years in London. In short, had he been articulated to an attorney—had he been apprenticed to a carpenter or a fishmonger, he could not have been subjected to a more degrading, a more expensive ordeal. Is this a state of things which is calculated to give satisfaction either to the student, to the public, or to surgeons and apothecaries, whose articles are so unceremoniously imposed upon them in the "recognised" system of medicine?

Why, we ask, if the private practitioner be endowed with sufficient acquirements, and be gifted with an adequate share of industry, to convey to his pupil an adequate knowledge of the various branches of medical knowledge; why, we ask, is he discouraged from pursuing a course which might prove in the highest degree advantageous to his own interests, as well as to the professional and moral welfare of the individual who is placed under his charge?

And pray, who are the practitioners whose abilities are spurned by the Colleges, and whose acquirements are made the subject of vulgar ribaldry by MACLEOD and the rest of his ignorant clique? It happens, strangely enough, that they are gentlemen who have endured all the tortures and the costliness of the certificate system, and have been proclaimed by the ruling authorities to be perfectly qualified to undertake the duties of medical practitioners. And who are the lecturers? Why, persons who, in point of legal professional qualifications, possess no higher, no better claims on public confidence. Yet in the one case, a "certificate" of three months' attendance on oral discourses, delivered daily, during a single hour, is "recognised," is received as entitling the candidate to possess the license or the diploma; whilst a testimonial of attendance during "five years" at the bedside of the sick, in the dispensary, in the laboratory, and in the botanic garden, of an able surgeon-apothecary engaged during the five years not only in the ordinary duties of his profession, but in conveying instruction to the mind of his industrious pupil, is rejected with contempt and scorn, and the hospital and "recognised" functionaries command such dirty miscreants as their toad-eating hack MACLEOD, to hold up and exhibit the private practitioner to the public, as a person who has not a sufficient knowledge of his subject to instruct a pupil in the mere practice of medicine. No more truly extortionable of the system of "cer-

tificates," and "recognition;" and it is marked by this striking peculiarity, that there is not connected with it a single benefit, and even a tendency to counteract the considerable disadvantages. If the governors of our colleges and medical companies had been stimulated in the performance of their duty by a generous desire to make the path of study smooth and easy to the student,—to afford to the surgeon in private practice a just reward for his assiduity in cultivating the minds of his pupils, and to maintain the public health on a secure basis,—every encouragement and inducement would have been held out to surgeons and apothecaries, to excite them to undertake, with promptitude and perseverance, the labour of giving the best instruction to all those students in medicine who might be placed under their roof, or within the limits of their control. If lecturers, by the mere habit of lecturing in a slovenly and formal manner, can acquire in the course of years a knowledge of the science of medicine which is not enjoined by persons similarly engaged, surely common sense would suggest the propriety of adding to the greatest possible extent to the number of teachers, and of widening the surface whereon they might exercise their beneficial labours. It is not our object to contend that A or B is qualified to instruct a student adequately in the whole vast field of medical science; but we contend that every private practitioner should enjoy the right of obtaining for his pupil an examination before those men who have been empowered by Parliament to protect the public against the evil practices of incompetent or unqualified practitioners. When our dastardly and contemptible opponents can show that such a privilege as this ought not to be placed under the control of surgeons and apothecaries engaged in general practice, it is possible that the revilers may cease to disturb their virtuous feelings, by discontinuing a practice with which they have long been so familiar, that of a wholesale traffic in falsehood.

It is, however, after all, not only amusing but delightful to witness the shifts to which the corruptionists, their abettors, are driven to sustain their tottering cause even for only a few months longer. All their endeavours, however, will prove unavailing. The fiat of public opinion has gone forth against the extortioners. The entire system of corruption has been exposed. Within a few months from this date it will disappear for ever, and,—

“Like the baseless fabric of a vision,
Leave not a wreck behind.”

In the parish of St. Clement Danes, a smart contest is now existing for the office of parochial surgeon. There are two candidates for the situation, Mr. COSGREAVE, who has held it for nine years, and Mr. DUNN, a surgeon who offered himself as a candidate on a former occasion. The claims of Mr. COSGREAVE are founded upon past services; those of Mr. DUNN rest on the principle that the office of parochial surgeon is one of honour, and not one of emolument, and that it should not be permanently held by one individual, whatever his merits,—whatever may have been the value of his labours. From this doctrine, which is advocated so zealously by Mr. DUNN and his friends, we dissent entirely; nor can we conceive that one more injurious to the interests of the poor, or more derogatory from the character of the profession, can be advanced by a medical practitioner. We take the question, therefore, between the two candidates—regarding both of them as eligible in point of medical rank and skill—to stand simply thus,—that if there be no well-founded complaints, no instances of culpable neglect, no charge of want of ability in the treatment of the sick poor, to be sustained—*proved*—against Mr. COSGREAVE, that gentleman, upon every principle of equity, of justice, and of good policy, ought to be reappointed to the vacant office. On the other hand, if accusations, such as we

have stated, can be sustained, then should Mr. DUNN, decidedly, be entitled to a preference. Is it, we would ask, to be tolerated, that the sick poor of our parishes are to be made the mere stepping stones to emolument or wealth? Are they to be made objects of sport for the gratification of ambitious feelings? Really, on reflection, Mr. DUNN must himself perceive that he has advocated a doctrine which strikes at the very happiness and well-being of the poor, and that he himself, at the end of a year of excessive labour and devotedness to the cause of the afflicted applicants for parochial aid, may be made the victim of a principle which we are certain he has thoughtlessly advocated in the present contest. If Mr. COSGREAVE is to be rejected in the absence of sustained complaint, why is any other officer to be permitted to continue in his post? If fidelity of service be no security for permanency of occupation, then, indeed, we have mistaken reform for change, improvement for alteration. It is said that the contest is a party one, and that Mr. COSGREAVE is supported by the Tories. The medical treatment of the sick poor, a party question! The announcement is too frightful to dwell on. Humanity and faction have no sympathies in common. If the reformers of Saint Clement Danes are desirous of proving that their love of alteration is more ardent than their desire for emendation, they will support Mr. DUNN—in the absence of established complaints against the claims of Mr. COSGREAVE. But if, on the other hand, they are anxious to sustain their character for humanity, and of showing the public that they are determined to promote the well being of the suffering poor who are committed to their charge,—that they are above all considerations of angry party politics,—they will, at the poll, support that medical officer who, during nine years, has discharged his duties in the parish and to the afflicted with humanity, industry, and

ACCOUNT OF THE

PARISIAN INSTITUTIONS FOR MEDICAL EDUCATION.

SESSION OF 1835-36, COMMENCING IN NOVEMBER 1835.

In the first number of the Volume of *THE LANCET* for the present year, we gave, according to our annual custom, an account of the different schools of medicine attached to and near the London hospitals. The approach of a new session in the school of Paris, now induces us to lay before our readers a review of the medical institutions which are devoted to the instruction of students in the French capital, for the benefit of those gentlemen who may intend to visit that capital for the purpose of completing their professional education as physicians or surgeons.

In London the number of medical schools is at once very great and extremely perplexing. With each hospital is incorporated a school, and near to it are numerous teachers possessing theatres or rooms for lecturing, extensive changes taking place amongst them every year. In Paris there is but *one* school of medicine, the 'Faculté de Médecine de Paris.' This body is composed of a dean, two assessors, and twenty-four professors, who are all chosen by concours. The locale of the faculty is a handsome quadrilateral building, which contains a museum, a library, cabinets of botany, surgical instruments, and every other requisite for instruction, and an immense amphitheatre, in which all the lectures of the faculty are delivered, and which is capable of containing from 1500 to 2000 persons.

The instruction of the medical youths in Paris is confined, in a great measure, to the twenty-four professors who compose the school, no private teacher being permitted to lecture, without express permission obtained from the minister on the recommendation of the dean of the faculty. Dissections are not permitted to be prosecuted in any part of Paris, except in the two establishments devoted to anatomical purposes, which are attached to the institution of the faculty. However, the authority to teach is granted readily to any respectable medical man; and students, as we shall have occasion to notice by and by, may receive abundant private assistance in their anatomical studies, at the two immense establishments of Clamart, and the *Ecole Pratique*.

The medical session in Paris commences on the first of November, and terminates on the first of September. It is not divided, as in London, into Winter and Summer Sessions, but the greater part of the professors continue to lecture during the whole season. The following is a list of the professors of medicine, and the subjects upon which they lecture &c.

FACULTY OF MEDICINE—SCHOOL OF MEDICINE.

Anatomy.....	{ M. Cruveilhier (physician to <i>Salpêtrière</i> , and lately appointed professor of Pathological Anatomy)	Lectures delivered gratuitously to the audience.
Physiology	M. Bérard	Ditto.
Medical Chemistry	M. Orfila	Ditto.
Medical Physics	M. Pelletan	Ditto.
Botany	M. Richard	Ditto.
Pharmacy	M. Deyeux	Ditto.
Hygiene	M. Desgenettes	Ditto.
of Medicine {	M. Andral (physician to the Hospital <i>La Pitié</i>) and M. Dumeril.....	Ditto.
	{ M. Marjolin (surgeon to the Hospital <i>Beaujon</i>) and M. Gerdy (surgeon to the Hospital <i>St. Louis</i>)	Ditto.
	{ M. Richerand (surgeon to <i>St. Louis</i>)	Ditto.

Charité, *L'Hôpital de l'École* (the clinical hospitals), the *Hôpital des Enfants Malades*, the *Veneréal Hospital*, and the *Hôpital St. Louis*.

THE HOTEL DIEU.

This hospital is situated at a distance of about ten minutes walk from that part of the city in which the students generally reside. It contains one thousand beds, distributed in

nineteen large wards. The service of the hospital is performed by eleven physicians, three surgeons, nineteen internes (corresponding to our dressers), and 84 externes, and students in pharmacy, who act as apothecaries. The number of patients received during the year averages about seven-teen or eighteen thousand. The following table exhibits the days and hours on which the medical officers visit the hospital, with such other particulars as it is necessary for us to mention.

Surgeons.	Lecture Days.	Hours.	Fees.
M. Roux	Clinical Lecture every day except Thursday —	7 to 8 a.m.	None.
M. Sanson		6 to 7 a.m.	None.
M. Breschet		8 to 8 a.m.	None.
<i>Physicians.</i>			
M. Chomel	Mon. Wed. and Fri.	7½ to 8½ a.m.	None.
M. Caillard	—	8 to 9 a.m.	Lectures occa- sionally from the remainder
M. Recamier	—	7 to 8 a.m.	
M. Petit	—	8 to 9 a.m.	
M. Magendie	—	7 to 8 a.m.	—
M. Husson	—	7 to 8 a.m.	—
MM. Piorry and Bally ..	Clinique Tu. & Thurs.	7½ to 8½ a.m.	—
M. Guineau de Mussy ..	—	7 to 8 a.m.	—
M. Honoré	—	7 to 8 a.m.	—

The above hours are those of attendance during summer. In winter the time is generally one hour later. The clinical lectures commence immediately on the visit of the surgeon or physician.

The only physician at the Hotel Dieu, whose practice is much followed by the pupils, is M. Chomel, and it is but justice to say that the reputation which he has obtained as a clinical teacher is richly deserved. The other medical wards are comparatively deserted. However, valuable information may be collected by the more advanced student, in the wards of M. Magendie and M. Recamier, which always contain many highly interesting cases. Clinical surgery, formerly professed with such *éclat* by Dupuytren, is now taught by M. Roux; but the latter, though a brilliant

operator, will never, we fear, be calculated, as a lecturer, to sustain the reputation once possessed by the School of the *Hotel Dieu*, as the first surgical clinique in Europe. We should mention that a clinique of diseases of the chest is entrusted to M. Sanson, and that a highly useful course on the application of the stethoscope in diseases of the chest is given at three o'clock by an interne, M. Roger, in the wards of M. Recamier. During this course, which costs the moderate sum of one pound, the pupils have an opportunity of daily applying the stethoscope in a variety of thoracic diseases, under the direction of one who is fully competent to instruct them. Similar courses have been given at *La Pitié*, at *La Charité*, and at *St. Louis*. The operating day for the clinical patients is Saturday; for the other wards there is no fixed day.

HOPITAL DE LA PITIE.

Physicians.	Surgeons.	Hours of Visit and Clinique.
M. Andral	8 a.m. every day.
—	M. Blandin ..	7 a.m., clinical observations 3 times a week.
M. Dr. Chatelet	7 a.m.
.....	7½ a.m.
.....	M. Lisfranc ..	8 a.m., clinical lecture daily.
.....	7½ a.m., clinical observations daily.
.....	8 a.m.

The *Hopital de la Charité* is situated to the south of the *Jardin des Plantes*, about twenty minutes walk from the *École de Médecine*. It contains more than 600 beds, and receives annually about 8 or 9000 patients. We are not aware that any fixed days are appointed for operating at the hospital, but the student has always sufficient notice of the most important operations which are to take place.

It is unnecessary to make any comment on the names of MM. Andral, Lisfranc, or Louis. The latter is the most minute observer of disease in France, and is chiefly followed by the English and American students. M. Lisfranc has long been the most popular teacher of surgery in Paris, but his wards are always so crowded, that we would

almost advise the English student to follow any other surgeon. M. Andral passes through his service without ever making a remark: his wards are therefore more fit for those who have already completed what is called their education, than for students who require the hand of a master to guide them. The neighbourhood of the hospital of *La Pitié* is perhaps the best situation in Paris, in which a student can fix his temporary abode. Comfortable board and lodging may be obtained at any of the *pensions* in the rue Copeau, rue neuve St. Etienne, rue des Postes, &c., for from sixty to eighty francs a month (from 2*l.* 10*s.* to 3*l.* 5*s.*). The dissecting-rooms at Clamart are within a few minutes walk, while, close to the hospital, indeed on the opposite side of the street, is the *Jardin des Plantes*, with all its *agréments* and its boundless scientific treasures.

HOPITAL DE LA CHARITÉ.

Physicians.	Surgeons.	Hours of Visit and Clinique.
—	M. Guérbois.	—
M. Fouquier.....	—	7 a.m., clinical lectures at the beds-side of the patient.
M. Maury.....	—	Idem.
—	M. Velpeau..	7 a.m., clinical lectures daily.
M. Rulhiér.....	—	—
M. Rayer.....	—	—
M. Bouillaud.....	—	7 a.m., clinical lectures three times a week.

The number of patients contained in this hospital amounts to about 500; its annual population is from 5000 to 6000. The operating days still continue, we believe, as in the time of M. Roux, to be Tuesdays and Saturdays. Students who propose attending the clinics of M. Velpeau or M. Bouillaud may dissect at the *École Pratique*. The consultations of M. Rayer on diseases of the skin are also well worth attending.

This hospital is the next largest in Paris to the *Hôtel Dieu*, but its situation, which is at the northern extremity of Paris, renders attendance on its practice very inconvenient for the student, except during the summer months. It contains more than 700 beds,

receives annually from 5000 to 6000 in-patients, and affords relief to more than 25,000 out-patients. The clinical lectures of M. Alibert and Biet are followed by all those students who desire to become acquainted with the various forms of cutaneous disease; while the lectures and practice of M. Lagol afford numerous advantages for the study of scrofula. Students who follow the other hospitals, which are situated more near the school of medicine, and the anatomical amphitheatres, will perhaps find it most advantageous to follow merely the clinical lecture which M. Alibert gives once a week, on Wednesday mornings, at 10 o'clock.

HOPITAL ST. LOUIS.

Physicians.	Surgeons.	Hours of Visit.
M. Alibert.....	—	10 a.m. Monday, Wednesday, Friday, and a Clinique every Wednesday.
M. Biet.....	—	9 a.m. Clinical lectures 3 and 4 times a week.
—	M. Gerdy.....	8 a.m. Daily.
M. Emery.....	—	8 a.m. Daily.
—	M. Jobert....	8 a.m. Daily.
M. Lugol.....	—	9 a.m. Clinical lectures only during the summer.
—	M. Richerand	Attends every two weeks.

THE VENEREAL HOSPITAL.

Surgeons.—M. Callier, M. Ricord, and M. Mance; attendance at 7½ a.m.—Clinical lectures occasionally given.

This fine hospital, containing more than 600 beds, for patients of both sexes, is situate in the Rue des Capucins, not very far from the School of Medicine. It affords the best opportunities for the study of the venereal disease; and although the number of students admitted to the practice is limited, M. Ricord, whose politeness to foreigners is proverbial, grants the latter every indulgence in his power. Thursday, being a kind of idle day at the great operating hospitals, is the day which is generally chosen by strangers and students for "a visit to the Venereal." M. Ricord from time to time publicly examines the whole of the female patients under his care, with the speculum, when a "turn up" takes place which visitors would certainly see in no other country.

HOPITAL DE L'ECOLE.

This small hospital, which has just been finished, occupies one side of the *Place de l'Ecole de Medecine*, immediately opposite the Ecole itself. It contains about 150 beds, distributed amongst medical, surgical, and obstetrical patients.

Physician.—M. Rostan; Clinical Lecture three times a week at 7 a.m.

Surgeons.—M. Cloquet; Clinical Lecture three times a week at 7 a.m.—M. Dubois; ditto at 8 a.m.

This hospital is specially destined for the instruction of students who have entered on their "fourth year," but every student is requested to attend the practice without discrimination. The clinique of M. Rostan is, perhaps, one of the most instructive that the student can follow. Not content simply with remarks which are full of interest, delivered at the bed-side, M. Rostan frequently selects a pupil from amongst the crowd which follows him, requests him to examine the patient, and requires a diagnosis of the nature of the disease, and a plan of treatment, with the reasons for its adoption. Thus a regular consultation is held in the presence of the pupils, who become accustomed to form a judgment for themselves, and are not induced or compelled, as is too often the case in clinics, to adopt implicit opinions which are given out by

admitted. We are not, however, to accuse the hospital functionaries of selfishness on this account. The number of beds appropriated to accouchements, in this small hospital, is not sufficient to satisfy the wants of French students themselves. Foreigners cannot, therefore, complain with any justice. It is right, however, to mention that all students (a circumstance which is not generally known) are permitted to attend the clinical lectures of M. Dubois, and to follow his visit through the wards, where he frequently makes some clinical observations, the only privilege reserved for the French student being that of delivering the women, and practising the toucher.

We may here remark, *en passant*, that midwifery is the only branch of medicine which is not well taught in Paris. Let no foreigner who desires to pay special attention to this branch of the science, think of remaining an instant in the French capital, but proceed at once to Heidelberg, or, still better, to Vienna. There are, indeed, numerous private teachers of midwifery at Paris, who give a course of lectures for five or six weeks, during which they deliver two or three women in presence of the class, and demonstrate the positions of the fetus and the mechanism of labour upon what are called "mannequins," i. e. a stuffed pelvis, with an artificial fetus. The pupil also has an opportunity of practising the toucher a certain number of times during the course, but as the same women are "touched" in nearly all the theatres, and frequently we believe by several different classes in the same evening, the state of parts is such that very little can be learned from them.

HOPITAL DES ENFANS MALADES.

Physicians.—M. Jadelot; at 10 or 11 a.m.; very irregular. M. Guersent; at 9 to 10 a.m. M. Baudelocque; at 8 to 9 a.m. M. Bonneau; ditto a.m.

Surgeon.—M. Baffos; at 6 to 7 a.m.

This hospital contains 560 beds, about 500 of which are appropriated to medical diseases. The service of the hospital is divided into four parts; viz: the acute diseases of boys; the acute diseases of girls; the scrofulous patients, and the skin diseases, principally comprising the itch. Each physician takes a division for six months, at the expiration of which he exchanges it for another. The great distance of this hospital from the school of medicine is, perhaps, the reason why it is comparatively deserted by the students. It is a rarity to see the physicians of the acute wards attended by more than four or five pupils; however, it affords a good opportunity for studying the diseases of children,

accouchement, which is the province of M. Paul Dubois, who is to French students upon their fourth year of study in medicine are not

some difficulty in feeling the stone, but having quickly afterwards succeeded in his search, he introduced a small forceps and grasped a calculus, which was so friable that it broke in the blades of the instrument; a portion was removed immediately, the remaining parts in the course of a few seconds. On introducing the searcher, another stone, of larger dimensions, was detected, and attempted to be grasped by the forceps several times, but without success, as it kept slipping from the hold of the instrument. Both the small and large forceps were several times employed, and a firm grasp having been obtained with the latter, the stone was about to be removed, when the incision was found to be too small to allow its passage outwards to be effected. The operator now introduced the knife and divided the right side of the prostate, when the stone was immediately removed; not more than two tablespoonfuls of blood were lost in the operation. The stones were of the lithic-acid species, with an outer coating of the triple phosphate. The first stone was about one inch and a half long and half an inch broad; the other was about two inches long and one broad. The operation lasted rather more than eleven minutes.

Mr. LISTON afterwards remarked that the second stone was so situated that he found it impossible at once to grasp it. The fact of the patient's not having been able to retain any urine accounted for the difficulty in seizing and disentangling the last stone from the fundus of the bladder. No parts had been cut beyond what was absolutely necessary, and the patient had lost less than three ounces of blood.

12. Going on very comfortably; catheter removed to-day; urine getting clear.

15. Some medicine had been given to open the bowels, which operated most unexpectedly in a copious manner, and left the patient in a very weak state. Stimulants were at once exhibited, but notwithstanding their employment he gradually sank, and died at an early hour this morning. We can only remark that eighty years is not an uncommon age to close the life of a patient whether near or soon after an operation, which in this instance was admirably performed.

GASTRODYNIA TREATED WITH CREOSOTE.

Dr. ELLIOTSON, in his last lecture, referred to the case of Catharine O'Keefe, aged 47, who was admitted into the hospital under his care on the 25th of August last. She stated on her admission that she was married, and the mother of four children. She has not menstruated since Christmas. She began about nine years ago to experience severe spasmodic pains in the stomach, occurring in paroxysms of two or three hours duration, and at intervals

of one or two days. These attacks occurred invariably a few hours after dinner. Blistering, bleeding, and the administration of mercury to salivation on several occasions, had produced no relief from her sufferings, though on two occasions she has been perfectly free from pain for six months, but this did not appear to be the result of medical treatment. About nine months since she began to experience pain, and a sensation of weight between the shoulders. She was also troubled with sour eructations, and a burning pain along the œsophagus. On her admission she was quite free from pain when the stomach was empty, but her sufferings commenced as soon as she had taken food. When the pain attacked her, she could only lie on her back, in which position, indeed, she always was most comfortable. The abdomen was very tender to the touch. The pain was always relieved by hot ingesta; her pulse was 60 and small; her tongue covered with white fur; the bowels regular, the urine clear; appetite variable; headache.

Dr. ELLIOTSON thought the case a favourable one for the administration of creosote; he therefore ordered her to have two minims of that medicine every six hours, and placed her on a mild diet.

27. She complains of pain in the left shoulder shooting down the inside of the arm to the elbow; there is also slight pain when pressure is applied, upwards from under the diaphragm. The pain in the stomach is undiminished.

29. The creosote was increased to day to four minims: the pain in the shoulder and arm is relieved; that in the stomach remains the same; bowels regular; pulse 80.

Sept. 8. Since the last report the pain has occasionally been very severe; a day or two ago she was attacked in the following manner; her skin became very hot, succeeded by a profuse perspiration, which was followed by cold shiverings, which, after a short time, gave way to the natural temperature. To-day the pain in the stomach is more severe; she has scarcely any rest at night; her appetite is gone. Pulse 78. Dr. ELLIOTSON considered that the medicine had not had a fair trial. It had been gradually increased to eight minim doses, and he now ordered ten minims to be taken every four hours.

17. The pain is less. She has noticed a considerable increase in the quantity of her urine since taking the medicine. She now takes fourteen minims every four hours, and oftener if the pain returns. She did experience much benefit from the medicine taken during the pain.

25. Has been improving. She is now almost free from pain, and the epigastrium is free from pressure. Her tongue is good, the pulse 70, and full.

Oct. 6. Her dose of creosote has been gradually increased to eighteen minims, with decidedly good effect. Indeed she is so much better as to be placed on the books as "cured," but there is occasionally a very slight pain in the stomach.

Dr ELLIOTSON remarked that this was a case which was not likely to be relieved by blistering, bleeding, or mercury. Aromatics, he observed, were generally employed with benefit, and pressure usually produced relief during the paroxysm. There was no doubt that the pain was exceedingly severe in these cases. He had never heard of a case in which an attack was fatal, but he thought such a result possible. As to the remedy administered, of course it would not be necessary to carry it to the extent in all cases to which it had been employed in the present instance.

CLINICAL LECTURES.

In commencing the clinical lectures for the session, Mr. LISTON remarked that a prefatory address was unnecessary, the lectures not having been discontinued during the summer, and he was now continuing, not commencing, a course. Twenty years ago, when he also was a pupil in London, not a single clinical lecture on medicine or surgery was delivered in the metropolis; whilst in continental schools, and in the once celebrated school of Edinburgh, the greatest attention was bestowed on that admirable method of medical instruction. Of late, however, a wonderful change had been wrought here. Pupils had been taught to appreciate clinical instruction, and the medical officers of the hospitals (many of them probably reluctantly enough) had yielded to the demand, so that at every London Hospital, large and small, clinical lectures were at least promised, both by physicians and surgeons. At this hospital, not the smallest, the students might rely on the promise being redeemed. He (Mr. L.) had for a series of years been engaged in delivering clinical lectures before he was requested to fill the situation of surgeon here. He had long been partial to this kind of teaching, and as it happened that he was not otherwise engaged at this school, they might be assured that he would give, at the least, his

lectures are given at this week, two medical, with punctuality.

LOCK HOSPITAL.

CASES OF GONORRHOEAL DISCHARGE, ACCOMPANIED WITH CHYLOIDOMA AND CONDYLOMATOUS ULCERATION.

CASE I.—*Amelia Doubleday*, aetat. 22, was admitted March 13th, under the care of Mr. WALKER. She has been married five years, and has two children. She has had her present complaints for three months, which began with scalding, and were followed in the course of a week by discharge and sores, which have lasted for three weeks. About six weeks since she took some medicine, supposed to be balsam of copaiba, three times a day for three weeks, which did her no good.

She has now a profuse thin yellow discharge from the vagina, there is a superficial gray sloughy surface of ulceration covering the entire perineum, the opposed surfaces of the nates, the integuments, labia, &c., particularly at the superior commissure and in the commissure between the nymphæ and labia. The nymphæ are much enlarged, the inner surface of the left is excoriated. Her health has been very good, and she has been pregnant three months. She was ordered to take a *Senna Draught*, and to have the sloughy ulcerated parts washed with *Black Lotion*.

15. *Washed Sulphur* ʒj; *Carbonate of Magnesia* ʒij; to be taken twice a day.

16. There is much less discharge, and the greater surface of the ulceration has healed.

21. She complains of headache to-day; skin hot, and bowels confined. *Senna Draught*.

22. *Black Lotion* and *Linseed Poultice* to the ulcerated parts.

23. *Vespere*. The abdomen has been very much enlarged to-day; there is great abdominal tenderness on pressure, which appears to be dependent upon hysteria. The tongue and pulse are natural. To take the *Chalk and Catechu Mixture* and a *Rhubarb and Magnesia Draught*, with ten drops of *Tincture of Opium*, early to-morrow morning. Omit the *Washed Sulphur*.

24. The draught has given her great relief, the bowels not having been painfully acted upon; there is much tenderness of the abdomen, but no pain. The tongue is furred, there is headache and thirst, and the pulse is natural.

She now took *Culoael* and *Opium*, which she continued with much benefit for some time. She then took *Plummer's Pill* and *Sarsaparilla*, until

May 8, when "the report in the case book" states her to be much improved, and that the *Plummer's Pill* was discontinued on account of headache. Some hemorrhoidal which have troubled her have

completely disappeared under the Confection of Black Pepper.

21. The gums are tumid and vascular and very tender; there is also a white sloughy spot of ulceration on the anterior part of each tonsil. This was ordered to be touched by the Nitrate of Silver.

29. The throat is quite well. The ulceration over the labia, perineum, &c., is quite healed.

From this period up to the time of her leaving the hospital "cured," no event occurred to retard her perfect recovery. She was delivered of a male child the day after our last date. The child had a slight erysipelatous blush over the right side of the neck and ear, which was removed by slight purgation with castor oil, and on the 24th June she went out quite well.

CASE 2.—Sarah Blake, ætat. 19, admitted, March 27, under Mr. WALKER. Her present symptoms came on about nine weeks since, with gonorrhœal discharge, scalding, &c. She has had condylomata for a period of five weeks. She has had only one connexion, nine weeks since. There is at present a profuse, thick, dark, yellow discharge from the vagina, with excoriation of the orifice. The condylomata are situated on the outside of each labium, between it and the thigh; there are some also on the perineum and nodes; some are in an incipient, and others in a full state of ulceration. The right tonsil of the throat is enlarged, and covered by a slight superficial ulceration. Her general health is good, the bowels are confined. The catamenia are regular, and commenced at fourteen years. A *Senna Draught* to be taken immediately, and a *Diluted Solution of the Acetate of Lead* to be applied to the parts ulcerated.

April 3. The vaginal discharge is less in quantity, but there is much excoriation of parts, with some ulceration on the right side of the orifice of the vagina. The right tonsil is less swollen; the ulceration covering it is healed; the bowels are quite regular. *Powdered Cubebs* ʒij four times daily.

12. The discharge has rather increased in quantity; the ulcerated surface has healed, but there is still some excoriation around the meatus urinarius. The right tonsil is looking better, and has a more healthy appearance; there is some vascularity about the fauces. The medicines were ordered to be continued.

17. Catamenia are present; the medicines are ordered to be intermitted; in other respects progressing favourably.

24. The vaginal discharge has been more profuse since the *cubebs* has been omitted, and she complains to-day of some headache. There is intertrigo in the commissure behind each labium, with considerable vascularity and excoriations of the vagina. The *Powdered Cubebs* to be resumed in ʒij

does three times daily. The vagina to be injected with a *Diluted Solution of the Acetate of Lead* in the proportion of gr. iv to ʒi.

31. The discharge has very much improved; there is still some vascularity, but less excoriation of the vagina. The *Powdered Cubebs* was ordered to be omitted, and a *Fusion of Cubebs* used instead, of ʒi to ʒij of boiling water, as an injection.

May 6. The discharge has become much worse since the internal use of the *cubebs* has been discontinued. The bowels are confined; the tonsils have nearly regained their natural size.

10. The symptoms remaining much the same, she was ordered the following vaginal injection:—*Muriate of Ammonia* ʒij; *Water* ʒj; to be used frequently.

15. The injection has been of great service, the discharge has nearly ceased, and what remains is of a pale-yellow colour.

21. The discharge has remained stationary for a few days. She complains of headache and loss of appetite. The injection to be increased in the proportion of ʒss to ʒj. *Calomel* and *Antimonial Powder*, of each two grains, to be taken to-night at bedtime.

29. On examining the vestibulum there is some slight vascularity, but all trace of discharge is gone. She was discharged cured.

CASE 3.—Bathia Mitchell, ætat. 24, admitted on the same day with the above patient. Her complaints commenced with discharge and scalding, which she has had for four months. She has had condylomatous ulceration for three months. Her throat has never been affected; there is at present an extensive condylomatous ulceration occupying the labia, which are thick, hard, and swollen, this extends also to the inside of the thighs, the perineum and nates, going behind the anus; there is a profuse thick yellow discharge from the vagina; the right tonsil is enlarged and slightly ulcerated; the health is quite good; the bowels are confined; the catamenial discharge, which commenced at sixteen, is regular; the same preliminary treatment of a purging *Senna Draught* and the *Black Lotion* to the ulcerated parts was adopted, and on the

29th, she began using the *Oxymercurate of Mercury Lotion* in the proportion of gr. ss to ʒi, and took *Washed Sulphur* ʒj twice daily.

April 1. She was ordered to take the *White Mixture* ʒiss * every night at bedtime, and to go on with her other internal and external medicines.

3. The condylomata are many of the ulcerations have ulcers occurred in the

* The *White Mixture* consists of Magnesia, sulphate of magnesia, water.

matous swelling, and were different from the common condylomatous ulceration, as being attended with a loss of substance, and presenting a depressed surface. The vaginal discharge is white in colour and small in quantity. The ulceration on the tonsil is healed; on the upper part there is seen a white elevation, having the appearance, but not the entire character, of a pustule; the bowels are regular. She is to continue the use of all her medicines.

8. The tonsillar ulceration has healed, the white pustular appearance upon it resembles a warty excrescence.

12. The condylomata are becoming flat, thickened, and have a bluish appearance; the vaginal discharge is diminishing; the white body on the tonsil is irregular upon its surface, and hard to the touch.

19. The condylomata are nearly all gone, leaving behind some few spots of discoloration. To continue her medicines.

21. The wart on the tonsil presents the same appearance; it is situated on the upper and inner part of the right tonsil, which is much enlarged, but not increased in vascularity; the left tonsil is also slightly increased in size.

24. She is convalescent, and is to leave the hospital.

She was re-admitted again with many of her old symptoms on Oct. 8th. She had been on the town for the last three months. She has now an abundant thick yellow vaginal discharge, which has lasted three weeks; and some condylomatous ulcerations for two weeks; the orifice of the vagina is vascular, and there is slight swelling and tumefaction of the left labium; there are numerous small circular condylomata, aggregated, but not confluent, over the region of the perineum, and on the inside of both nates; there is superficial ulceration, approaching to excoriation, of the skin around. The throat is preternaturally vascular, but she does not complain of any difficulty in deglutition. The right tonsil is enlarged, and bears the same warty growth (but smaller in size) alluded to when she was formerly in the hospital. Her general health is good, the catamenia are regular, and she has never been pregnant. She was purged with *Calomel* and *Rhubarb*, and *Senna Draught*, and the *Decoction of Tormetilla Bark* was ordered to be used as an internal injection and an external application. There was, however, no *Tormetilla Bark* in the hospital, and the *Saturine Lotion* was ordered instead. She proceeded with this for some time, and on going round the wards one day we learnt from the nurse that she had left her legs and was off.

Case 18, admitted 18th June, 1844. Cases under the care of Mr. WALKER. She was on the town four months;

her present complaints began with a discharge two weeks since; scalding of the urine, with swollen labium and sore, followed in a week afterwards. There is now a profuse gonorrhoeal discharge from the vagina, with much scalding in micturition. There is a patch of sloughy condylomatous ulceration in the commissure between the right labium and thigh, with much swelling and redness of the immediately contiguous parts, extending to the perineum and nates. Her general health is good, but the bowels are much confined; both tonsils are enlarged, more particularly the right one, around which there is some inflammation and ulceration; the catamenial discharge has been absent three months. *Black Wash* was ordered to be applied to the ulcers, and the *Acetate of Lead Lotion* to be used as an injection.

April 3. The vaginal discharge is less, and is white in appearance; the scalding in micturition is gone; the condylomatous ulcerations are nearly healed; the inflammation of the labium has subsided, leaving behind much thickening and induration of parts; the bowels have been regulated by the hospital *Senna Draught*; on the surface of each tonsil there is a superficial spot of yellow ulceration; there is an ulcer of an oblong form on the inside of the left labium, it is red and granular, and the edges are slightly elevated. This has formed since her admission into the hospital. Mr. WALKER ordered the *Black Wash* to be applied to it.

12. There is to-day less thickening and induration of the labium. The condylomata have been healed some days, but have left behind them a blue thickened appearance of the skin. Both tonsils are enlarged and swollen, and covered with superficial white ulcerated surfaces; the ulcer on the labium is less inflamed, but still florid.

19. The tonsillar and labial ulcerations present much the same appearance as at the last report. The *Red Lotion* was ordered to be applied to them.

24. The inner labial ulcer is much in the same state; the tonsils (particularly the right one) are larger; the general ulcerative surface is healing; some small open patches are still left.

30. The ulcers are looking better, the margins are tumefied. The *Nitrate of Silver* was ordered to be applied to them.

May 8. The inner labial ulcer is nearly healed; there is much vascularity of the vestibulum; the thickening surface left by the condylomata is nearly gone. The right tonsil is much enlarged, and bears some slight ulcerative marks upon it. The yellow vaginal discharge continues. The *Solution of the Acetate of Lead* gr. vi to ʒj, to be used as a vaginal injection. She continued to lose many of her bad symptoms, and the report on the

29th was, that the white ulcerative ap-

pearance on each ~~it~~ ^{it} was gone, but that there was much pain on deglutition. The labial ulcer is improving under the occasional use of the *Nitrate of Silver*. The catamenial discharge has not appeared for five months. To continue the use of her medicines.

appearance. Her medicines were ordered to be discontinued, and on the following day she was discharged cured.

Mr. Wardrop's work on "Blood-letting" will be published on Monday next.

June 4. The tonsils have now lost all trace of ulceration, and present their normal appearance. The vaginal ulceration has healed, and the surface (with the exception of an increased vascularity) presents a healthy

Winds.—1 East; 5 West; 0 North; 12 South; 1 North-east; 7 South-east; 2 South-west; 2 North-west.

So much rain has not fallen in September since 1829, and the mean of the barometer was lower than at any time since 1831, while the maximum was below that of any period in the same month during the last twelve years. The month was colder than that of September 1834, and the mean temperature was below the average of the last twelve years. Thunder was heard on the 9th, 23rd, and 26th. On the two former days lightning was seen. On the evening of the 9th, the most brilliant Aurora Borealis which has appeared here since the 7th of January 1831 was observed;—the whole N.W. quarter of the heavens was illuminated by a pale yellow light, from which rays of near colour shot forth, extending beyond the zenith. These appearances continued a space of nearly two hours. On the 13th, the Aurora was again seen, and was of a red tint, and reached nearly to the zenith, but was not so long as on the 9th. The Wind on both occasions was fresh. These phenomena were succeeded by rain.

PATHOLOGICAL ANATOMY.

PATHOLOGICAL Anatomy is treated in this country with a degree of neglect which can be explained only on the supposition that the importance of its study is generally unknown. We have, indeed, a few distinguished men amongst us who labour to support the national reputation on a level with that of other European nations, but the great mass of medical men, through the imperfect precepts of their teachers, or an ill-founded fear of inability to acquire a sufficient knowledge of morbid anatomy, or under the culpable reflection that if they simply tread in the steps of their fathers they will do well enough,—this class of the profession continue to practise medicine purely in an empirical manner, and would never contribute to the advancement of the science were each to realise the Spanish compliment, and live a thousand years. With such examples, however, before them as are to be found in the “high places” of medicine, what have we to expect? Yet that it is time such a state of things should cease, and that farther and more extended efforts should be made to place medicine on a footing with the other sciences, who is “conservative” enough to deny? “Exact” we may never call the science, but we are satisfied that a searching examination into the operation of those causes which have retarded the progress of the science is enable us to show the ignorance with which it

has advanced, and the imperfections which are everywhere confessed to exist, depend not so much on the impossibility or the difficulty of raising medicine to an equality with the precise sciences, as on the manner in which it has hitherto been studied, and the obstacles which have been thrown in its path by those very persons who are most interested in the perfectibility of medicine. The mathematic and algebraic arts are based on fixed principles, and their elements, if we may so call their symbols, are passive and obedient agents in the hand of the professor who works them. But what would be the consequence if $x^2 + 2xy + y^2$ could say to the unfortunate algebraist, “Nothing know you of your business. My root no longer shall you work. I will depart to S. or to L.” Or what answer could we expect from a mathematician were we to require him to determine distances with but two angles, and without a side of the triangle? It is thus with medicine. The great mass of the community, so long as they remain in ignorance, will resemble the refractory symbols of the square root, and counteract every effort at a solution of the grand problem of medicine; while those who neglect pathological anatomy, commit an error analogous to trigonometrists who would say “Give me two angles and I will find you the side.”

The practice of medicine consists of four parts:—1. The observation of external phenomena, or symptomatology. 2. The observation of internal phenomena, or pathological anatomy. 3. The study of the connexion between the signs and their causes.

4. And, finally, the administration of medicinal agents, or therapeutics.

Of the four different parts, the first and last require the least degree of talent for their cultivation. Any person can observe and note down symptoms. Symptoms can never be observed too closely, for although several external phenomena may present themselves which are, apparently, of little note or value, they should, nevertheless, be observed. They are abnormal appearances, and although the relations between cause and effect may now be hid, it may at some future time be discovered. Thus the sudamina and rosy spots which so peculiarly characterize typhoid fevers, were no doubt observed many years ago, but the idea that they were insignificant phenomena led to their neglect; whereas now they form a very principal element in the distinction of that species of fever.

The administration of medicine, or the therapeutic portion of the art of medicine, does not, we have said, require the exercise of much talent. The statement demands a few words of explanation. We fear, from the nature of things, that this, the practical part of medicine, will ever remain empirical. The efficacy of medicines in disease can never be established by *a priori* reasoning. We can, therefore, only administer them with caution. We here speak of new medicines, and not their effects; but to advance medicine by observation of the effects of medicinal agents, it is obvious that we should previously be thoroughly acquainted with the three other branches of medicine, especially with the doctrine of symptoms, and with morbid anatomy. In a word, that our diagnosis of disease should be as perfect as it can possibly be made. Without this perfection of diagnosis, the practice of medicine, instead of advancing with the experiments made in a therapeutic point of view, will naturally retrograde in direct proportion to the number of those experiments, for this simple reason, that a confusion of results is the consequence, and that it is impossible to see clearly through a multitude of conflicting statements. Hence, next to a careful ex-

amination of the patient at the bedside, the most important branch of medicine is pathological anatomy, and we trust that some persevering effort will be made to place this too long-neglected branch of medical education on a proper footing. There is not so much an absence of good works on pathological anatomy amongst us, original or translated as the want of a system of instruction, and of constant and efficient attendance in the dead houses of the hospitals. It is unnecessary to dwell on the common observation, "that pathological anatomy is of no use, unless connected with symptomatology." It is certainly studied with most advantage in cases where the pupil has been made acquainted with the previous history of the patient, has observed every stage of the case with care, and having become fully possessed of a knowledge of the external signs is ready to compare and examine them in connexion with the appearances which present themselves after death. This is the true way of learning morbid anatomy, and we earnestly recommend the rising generation of practitioners to avail themselves of every opportunity of this kind which may offer. They may be assured that thus (independently of the feelings of confidence in the practice of the profession, which will arise from a consciousness of knowledge of the nature of the changes that take place in the internal and invisible surfaces, nearly as complete as of those which pass before our eyes) the whole aspect of medical science will become changed, and the profession will rise in an instant from the depths of quackery to the rank of a noble science. In our hospitals, men of tried merit should preside, whose duty it should be to arrange the clinical cases, and examine the bodies of those who die. In some of the continental hospitals, there are young men expressly appointed and paid to fulfil this duty, and we believe, lodged in the hospitals, who not being distracted by the cares of an enormous practice, can devote their attention to the instruction of the pupils to an extent which non-resident hospital functionaries are not disposed to, and never will, give.

We are induced to make these remarks at the present moment, under the impression that we could not choose a more fitting time or place to draw the attention of pupils and conscientious observers to the subject.

ON THE NATURE OF
INFLAMMATORY FEVER.

By HENRY SEARLE, Surgeon, Kennington.

THE term "inflammatory fever," when properly applied, refers only to that general excitement which is preceded and accompanied by local inflammation. The terms "symptomatic," and "sympathetic fevers," "pyrexia," and "constitutional irritation," are used, synonymously, to designate inflammatory fever.

Whether inflammatory fever ever occurs idiopathically, has been a question of some controversy. It is admitted by some to occur, though seldom, in so simple a form as in the synocha of Cullen; but its appearance in the more complicated form of synochus, from which it in a few days becomes modified into typhus, is very generally acknowledged. It is however by no means proved that fever takes place without the existence of local disease as its exciting cause. Broussais, Clutterbuck and others, are opposed to the doctrine of idiopathic fevers; while Dr. Southwood Smith's dogma is—"There are no fevers but idiopathic fevers."

Inflammatory fever may assume a mild or a severe form. The former is simple, consisting in a general excitement of the nervous and vascular systems: the latter is more complicated, being, in addition to the local phlegmasia, accompanied by more or less disturbance of the brain, liver, stomach, or other organs; so that the worst cases may more resemble typhus than simple pyrexia.

The different grades of inflammatory fever do not always correspond to the degree of inflammation, since it frequently happens that, in cases in which no predisposition to fever exists, even an acute inflammation is unattended by any constitutional irritation; and, on the contrary, in cases in which the predisposition is very great, the slightest inflammatory disease gives rise to considerable pyrexia. It may therefore be inferred that the predisposing causes play a greater part in the production of inflammatory fever, than the inflammation itself.

The causes of inflammatory fever admit of being arranged into *exciting, predisposing, and secondary or perpetuating causes.*

Of exciting causes.—Those inflammatory affections which are the most painful, are the most productive of fever; and the pain of inflammation depends upon the texture, mechanism, and office of the parts, together with the intensity and extent of the inflammation. Thus, for example, which are not easily swelled,—parts which are easily compressed by the pressure of their contiguous parts, and organs which

are subjected to sudden compression and distention—as serous membranes, ligaments, and synovial membranes of large joints, the fauces, and the bladder—when inflamed induce more or less pyrexia. Severe and painful injuries also, as compound fractures, burns, &c., frequently produce considerable fever.

The more intense and extensive the inflammation, the more acute the fever: when, however, the pain is so acute as to overwhelm the powers of the whole frame, instead of a high degree of fever, the consequences are, as in very acute gastritis, a low pulse, and cold perspiration.

The *predisposing causes* are always general, depending upon the nature of the constitution and the state of the health at the accession of the local disease, and especially upon the management of the muscular power during its progress.

It is doubtful whether inflammatory fever ever arises in the absence of a predisposing cause, it being essential to the occurrence of this fever, that the frame be in an excitable state, which state is inversely proportionate to the muscular power. It is true that a very severe and painful injury often produces, even in a strong constitution, a certain degree of febrile excitement in a few hours; but may not this be ascribed to the sudden, although not considerable, exhaustion of the muscular power occasioned by severe pain? This, however, is, at most, an extreme case, and does not affect the general rule—that the lower the grade of muscular power, the greater the excitability of the nervous, and vascular systems, and, consequently, the stronger the predisposition to inflammatory fever. Hunter observes that "in inflammation, when the constitution is strong, then it will commonly be the most manageable, for strength lessens irritability." And according to Abernethy, "irritation is debility excited." Numerous eminent physicians and surgeons, however, are of opinion that there is no absolute debility when the febrile action is characterized by a frequent and firm pulse. A frequent pulse, in the absence of inflammation, is an admitted sign of debility; and the annexed table will show that the frequent, although energetic pulsation in fever, is indicative of excited action under reduced power.

That functional alliance exists between the nerves of sensation and those of motion, which, in the rising period of life, and in disease, places their respective powers in inverse relations. For example, very young infants possess the least degree of muscularity, and the greatest degree of sensibility of frame; and as the former increases, the latter diminishes, until the muscular system becomes fully developed, when they balance each other; this harmony is maintained so long as health is preserved, not only during the middle or stationary period of life, but

during that of decline, for, as the muscular power declines, the sensibility also becomes impaired. Again, women and persons of delicate frame, whose muscular system is not well developed, are highly sensitive; and whenever the muscular power is greatly reduced by venesection, spare diet, anxiety of mind or disease, the sensibility is proportionally increased. On the other hand, whenever sensation is accumulated by superexcitation, as by the influence of fear, excessive pain, &c., the muscular power is lowered. Instances may, however, be adduced, in which certain depressing agents, as intense cold, marsh miasma, opium, &c., diminish both the sensibility of the nervous, and the power of the muscular systems.

This law of inverse action obtains between the nerves of sensation and those of voluntary motion only. It does not involve those of involuntary motion, for the contractility of the heart and arteries always corresponds to the sensibility of the

nervous system, as the pulse faithfully indicates.

In accordance with these views, the following table is intended to exhibit a kind of analysis of inflammatory fever, by showing that, according to the condition of the muscular system, is the sensibility of the nervous; and that, according to the combined conditions of these two systems, the circulation becomes modified, so as to correspond respectively to them in the unexcited and the excited states of the body. Inflammation is made the chief exciting cause, in order to show by the pulse that inflammatory fever takes place inversely to the muscular power. Miscellaneous temporary exciting causes are also given, merely to afford an example of temporary general vascular irritation. At the lowest part of the table are exhibited exceptions to this law of inverse action between the nervous and muscular systems, showing that the nervous and the voluntary and the involuntary muscular systems are, under certain powerful agents, all depressed together.

CONDITION OF THE MUSCULAR SYSTEM.	SENSIBILITY OF NERVOUS SYSTEM.	EXAMPLES.	PULSE.
Least muscularity ... Highest degree.	Unexcited	Infants in health	Very frequent and small.
	Excited by inflammation	Infants with enteric ... not very fevered	Regular, small, and tense.
	Excited temporarily, as by spasms, &c.	—	Frequent, small, and tense.
Little muscularity ... High degree.	Unexcited	Persons of delicate frame	More frequent, full, and less soft.
	Excited by inflammation	—	Very frequent, small and tense.
	Excited temporarily, as by spasms, &c.	—	—
Considerable muscularity..... Moderate degree.	Unexcited	Robust persons in health	Natural.
	Excited by inflammation	Ditto, without pyrexia	Moderate, often slow and oppressed.
	Excited by inflammation	Ditto, with inflammatory fever	Very frequent, to hard, becoming
Ditto, suddenly reduced in power by loss of blood &c.	Very high degree.	Ditto, with inflammatory fever	Very frequent, to hard, becoming
Ditto, reduced in power	High degree	Unexcited	Ditto, considerable
Every degree of muscularity reduced in power....	Low degree	Depressed by marsh miasma, intense cold, opium, &c.	Exceedingly irritable, and therefore predisposed to inflammatory fever—viz. <i>mental anxiety, and the habit of inebriation.</i>
		Depressed by marsh miasma, intense cold, opium, &c.	Few persons, comparatively, are of perfect health. Consumption impairs the energy of the muscular system.
		Depressed by marsh miasma, intense cold, opium, &c.	the heart and bloodvessels.

The comparative view of the various conditions of the nervous and muscular systems, given in this table, greatly tends to illustrate the nature of inflammatory fever, and shows, at the same time, how much it hinges upon the deficiency in muscularity, or upon the sudden reduction of muscular power.

In infants, as is well known, a mere spark of internal inflammation will ignite the whole frame. In all persons except the aged, in whom sensibility has become much impaired, and even in those to a certain extent, the predisposition to pyrexia under exciting causes is proportioned to the deficiency in muscularity. Those, on the contrary, who are muscular and strong, will sometimes have a phlegmasia during several weeks, un-

accompanied by any constitutional excitement, so long as they observe their usual regimen, and are not subjected to such medical treatment as will deprive them of their muscular power.

There are other circumstances besides the sudden reduction of muscular power which will render a muscular frame exceedingly irritable, and therefore predisposed to inflammatory fever—viz. *mental anxiety, and the habit of inebriation.*

Few persons, comparatively, are of perfect health. Consumption impairs the energy of the muscular system, and the heart and bloodvessels.

whole frame morbidly sensitive. The mind becomes charged with apprehensions, and the feelings become readily irritated, the heart becomes subject to palpitations, and the bloodvessels sometimes allow hemorrhages to take place by transudation; the functions of the several organs of the body, particularly those of digestion, become deranged. In this predisposed condition of the frame, an attack of inflammation is very liable to occur, and which will certainly induce an acute form of pyrexia, which, if not soon subdued, will be accompanied by the wildest kind of delirium, grave functional lesions, and other signs of low typhoid fever.

The habit of *inbibition* produces a conditional kind of predisposition; for unless it be suddenly and greatly restricted, it does not generally create a predisposition to fever. The drunkard, when deprived of his accustomed stimulus, is deprived at the same time of his power, his muscular system becomes tremulous and feeble, and his whole frame irritable. If, then, he be subjected to privation during an attack of inflammation, he will, under this exciting cause, be highly susceptible of fever, which will be characterized by greater nervous than vascular disturbance, by delirium tremens, and generally by the absence of the hot skin of fever. The strictly antiphlogistic treatment almost invariably converts the disorder into a highly dangerous form of fever.

Secondary Causes.—During the existence of inflammatory fever, all considerable derangements of the visceral functions tend to perpetuate it, by giving support both to the predisposing and exciting causes. For example, an imperfect function of the brain and spinal marrow will prevent the due distribution of the nervous energy to the muscular system; an imperfect function of the lungs and of the other excretory organs, prevents that purification of the blood essential to the proper function of the nervous system; an imperfect function of the digestive organs deprives the body of its due nutrition so requisite to the maintenance of muscular tone. Derangements of the visceral functions not only become secondary causes of fever by reducing the muscular power, but frequently an additional source of excitement to the whole frame, especially to the inflamed part, thereby perpetuating both the local disease and the general vascular irritation. If an inquiry be made as to the origin of these functional derangements, it may be mostly to that system of treating inflammation, which suddenly reduces all muscular power. Sometimes a large and robust frame too near the action, aggravates both the inflammation and its accompanying

This view of inflammatory fever is not offered as entirely new, for it is universally admitted that a delicate and sensitive condition of body is favourable to pyrexia under the existence of inflammation; but notwithstanding the admission of this principle, it is most strangely lost sight of at the bed-side; and why? because the antiphlogistic is the fashionable system of treating inflammatory diseases, before which any principle, however sound, and although recognised, must fall prostrate, rather than be allowed to violate or interdict a system so sacred as the antiphlogistic. It is, however, hoped, that by invoking a more close attention on the part of the medical profession to the real causes of inflammatory fever, that their relative importance will be more duly estimated; that it will be seen that although the exciting cause, inflammation, is a *sine qua non* in inflammatory fever, yet that the predisposing are, in most instances, the causes which have the greatest influence in the production of fever, and, therefore, that the treatment should be so adapted that, while attempting to remove the exciting cause, it should not, at the same time, be calculated either to increase or to produce the predisposing causes of inflammatory fever.

INTESTINAL OBSTRUCTION

FROM

RAW WHEAT.

To the Editor of THE LANCET.

SIR,—Permit me to transmit to you the report of a case, wherein a fatal result was near occurring, from a habit on the part of the patient of eating raw wheat. I am, Sir, your obedient servant,

J. L. MCCARTHY, M.D.

Macroom, October 14, 1835.

On Thursday, the 8th instant, I was sent for to visit John Leary, *etat.* 35, living at Toames, three miles from hence, a steward in charge of a farm belonging to a gentleman of the name of Penrose. I found the man in bed, labouring under the most agonizing pains, which he referred to the anus, rectum, and loins. He was bathed in sweat; his countenance expressed the greatest anxiety, but he suffered no headache nor delirium. His tongue was coated with a thick white fur, but moist; there was no affection of the chest or of the respiratory faculties, nor any complaint of the stomach, but he had much thirst, urgent desire to urinate, and evacuate the rectum, without ability to effect either. The abdomen felt quite soft on pressure, except over the pu-

during that of decline, for, as the muscular power declines, the sensibility also becomes impaired. Again, women and persons of delicate frame, whose muscular system is not well developed, are highly sensitive; and whenever the muscular power is greatly reduced by venesection, spare diet, anxiety of mind or disease, the sensibility is proportionally increased. On the other hand, whenever sensation is accumulated by superexcitation, as by the influence of fear, excessive pain, &c., the muscular power is lowered. Instances may, however, be adduced, in which certain depressing agents, as intense cold, marsh miasma, opium, &c., diminish both the sensibility of the nervous, and the power of the muscular, systems.

This law of inverse action obtains between the nerves of sensation and those of voluntary motion only. It does not involve those of involuntary motion, for the contractility of the heart and arteries always corresponds to the sensibility of the

nervous system, as the pulse faithfully indicates.

In accordance with these views, the following table is intended to exhibit a kind of analysis of inflammatory fever, by showing that, according to the condition of the muscular system, is the sensibility of the nervous; and that, according to the combined conditions of these two systems, the circulation becomes modified, so as to correspond respectively to them in the unexcited and the excited states of the body. Inflammation is made the chief exciting cause, in order to show by the pulse that inflammatory fever takes place inversely to the muscular power. Miscellaneous temporary exciting causes are also given, merely to afford an example of temporary general vascular irritation. At the lowest part of the table are exhibited exceptions to this law of inverse action between the nervous and muscular systems, showing that the nervous and the voluntary and the involuntary muscular systems are, under certain powerful agents, all depressed together.

CONDITION OF THE MUSCULAR SYSTEM.	SENSIBILITY OF NERVOUS SYSTEM.		EXAMPLES.	PULSE.
Least muscularity ... Highest degree.		Unexcited	Infants in health....	Very frequent and small.
		Excited by inflammation	Infants with infantile fevers....	Rapid, small, and tense.
		Unexcited	—	Frequent, small, and soft.
Little muscularity ... High degree.		Excited temporarily, as by emotions, pain, &c.	Persons of a lean frame	More frequent, fuller and less soft.
		Excited by inflammation	—	Very frequent, small and tense.
		Unexcited	Robust persons in health....	Natural.
Considerable muscularity.....	Moderate degree.	Excited by inflammation	Ditto, without pyrexia....	Moderate, often slow and oppressed.
Ditto, suddenly reduced in power by loss of blood &c.	Very high degree.	Excited by inflammation	Ditto, with infantile fevers....	Very frequent, full and tense.
Do., reduced in power	High degree ...	Unexcited	Ditto, convalescent.	Frequent, full, and soft.
Every degree of muscularity subdued in power...	Low degree	Depressed by marsh miasma, intense cold, opium, &c.	Every description of persons in the first stage of idiopathic fever &c.	Slower, weaker, and sometimes slower than natural.

The comparative view of the various conditions of the nervous and muscular systems, given in this table, greatly tends to illustrate the nature of inflammatory fever, and shows, at the same time, how much it hinges upon the deficiency in muscularity, or upon the sudden reduction of muscular power.

In infants, as is well known, a mere spark of internal inflammation will ignite the whole frame. In all persons except the aged, in whom sensibility has become much impaired, and even in those to a certain extent, the predisposition to pyrexia under exciting causes is proportioned to the deficiency in muscularity. Those, on the contrary, who are muscular and strong, will sometimes have a phlegmasia during several weeks, un-

accompanied by any constitutional excitement, so long as they observe their usual regimen, and are not subjected to such medical treatment as will deprive them of their muscular power.

There are other circumstances besides the sudden reduction of muscular power which will render a muscular frame exceedingly irritable, and therefore predisposed to inflammatory fever—viz. *mental anxiety, and the habit of inebriation.*

Few persons, comparatively, can endure *mental anxiety*, and a small degree of perfect health. *Concussion* impairs the energy of the muscular system, and the tone of the muscles, and the heart and bloodvessels.

whole frame morbidly sensitive. The mind becomes charged with apprehensions, and the feelings become readily irritated, the heart becomes subject to palpitations, and the bloodvessels sometimes allow hemorrhages to take place by transudation; the functions of the several organs of the body, particularly those of digestion, become deranged. In this predisposed condition of the frame, an attack of inflammation is very liable to occur, and which will certainly induce an acute form of pyrexia, which, if not soon subdued, will be accompanied by the wildest kind of delirium, grave functional lesions, and other signs of low typhoid fever.

The habit of *inebriation* produces a conditional kind of predisposition; for unless it be suddenly and greatly restricted, it does not generally create a predisposition to fever. The drunkard, when deprived of his accustomed stimulus, is deprived at the same time of his power, his muscular system becomes tremulous and feeble, and his whole frame irritable. If, then, he be subjected to privation during an attack of inflammation, he will, under this exciting cause, be highly susceptible of fever, which will be characterized by greater nervous than vascular disturbance, by delirium tremens, and generally by the absence of the hot skin of fever. INTESTINAL OBSTRUCTION

FROM

RAW WHEAT.

To the Editor of THE LANCET.

SIR,—Permit me to transmit to you the report of a case, wherein a fatal result was near occurring, from a habit on the part of the patient of eating raw wheat. I am, Sir, your obedient servant,

J. L. MCCARTHY, M.D.

Macroom, October 11, 1835.

On Thursday, the 8th instant, I was sent for to visit John Leary, *etat* 35, living at Toames, three miles from hence, a steward in charge of a farm belonging to a gentleman of the name of Penrose. I found the man in bed, labouring under the most agonizing pains, which he referred to the anus, rectum, and loins. He was bathed in sweat; his countenance expressed the greatest anxiety, but he suffered no headache nor delirium. His tongue was coated with a thick white fur, but moist; there was no affection of the chest or of the respiratory faculties, nor any complaint of the stomach, but he had much thirst, urgent desire to urinate, and evacuate the rectum, without ability to effect either. The abdomen felt quite soft on pressure, except over the pu-

bic and left iliac regions, where distention of the bladder, the sigmoid flexure of the colon, and the rectum, could plainly be perceived.

On making an examination per anum, I found its verge considerably swollen and inflamed, with great contraction of the sphincters, and so tender and irritable, that it was with much difficulty that the patient would allow me to proceed with the examination. He said he had been ill during the last three days; that during the first and second days of his attack, he only felt occasional fits of pain in the anus and loins, but that for the last sixteen hours, or thereabouts, he was in extreme agony, with but occasional slight intermissions. He had not had an anal evacuation for the last four days, and from ten o'clock p.m. on the previous evening had not passed any urine up to the time when I saw him, which was one o'clock p.m. on the following day. He said to me, that being for some time previous to his illness superintending the thrashing out of a large quantity of Mr. Penrose's wheat, he had, as was often his habit, eaten some of the grain as he proceeded, and to that he attributed his illness. He went on the second day of his illness to the Macroom Dispensary, where he was ordered a dose of castor oil, but no effect followed its exhibition.

Having by mistake omitted to bring a catheter with me, I sent home for one, and in the mean time proceeded to examine the rectum internally. With considerable difficulty I introduced my little-finger, well oiled, into that cavity, and found it extremely distended. It was, in fact, completely blocked up with a hard mass of undigested wheat. The agony which the patient suffered from this exploration, forced me to desist for a short time, when I determined on attempting to extract some of the wheat from the bowel. I accordingly procured a small egg-spoon, and having well oiled the handle, introduced it into the rectum, and detached and brought away from the mass about two ounces of semi-masticated wheat. By this means I obtained a little more room, so that I was enabled to force into the rectum a few small pieces of mutton suet, which I allowed to remain until they had melted. This had the effect of lubricating the part and softening the contents of the cavity; so that on a second attempt with the spoon-handle I succeeded in clearing out about ten ounces more of the wheat, the patient all this time complaining of almost intolerable suffering. Having desisted for a time in order to allow him some rest, he felt an urgent desire to go to stool, but the attempt was unsuccessful, owing to the tenderness and constriction of the anus. He was, however, able to urinate, and voided about two and a half pounds of fluid.

On making my next examination, I found

that the attempts to evacuate the bowels had brought down more of the wheat into the rectum, which was again filled to distention, but the mass was not so hard as in the first instance; and on again operating, I succeeded in removing about twenty ounces more. The patient now expressed himself as much relieved. I had by this time in all brought away about two pounds of wheat.

As I found his pulse full, quick, and bounding, I bled him to xxxv , when he became faint. I then had the rectum staped for about an hour, and gave him a draught containing an ounce of Castor Oil, fifty drops of Tincture of Henbane, and an ounce of Cinnamon water. Half an hour afterwards an enema was administered, followed by a purgative draught. Six hours afterwards I found him free from pain, and in a sound sleep. His bowels had been much affected by the enema and medicines, and an immense quantity of wheat, with some white starchy stuff, had passed from his bowels. The anus continued tender for a few days, but by keeping the bowels soluble with small doses of the Magnesian salts, he perfectly recovered.

SALIVARY CONCRETION IN THE SUBMAXILLARY DUCT.

To the Editor of THE LANCET.

SIR,—Should you consider the following case worthy a page in your widely-circulated and valuable Journal, the insertion of it will greatly oblige your obedient humble servant,

W. A. ELSTON, Surgeon.

Braybrooke, Northamptonshire,
Oct. 20, 1835.

James Whitehead, a young man about twenty years of age, called on me, Sept. 4, for my advice respecting a swelling on the right side of his neck, of which he had been the subject at times for four years, but which within the last week had considerably increased in size, and become exceedingly painful.

On examination, I considered it, from its situation, to be an inflamed and considerably enlarged submaxillary gland. It was very painful on being touched, and the patient was the subject of a high degree of fever. I ordered eight leeches to be applied to the tumour, and gave him a calomel bolus and a black draught, with a continuation of a saline aperient mixture. On the 10th I saw him again, and found the swelling still painful, and somewhat increased. I ordered the leeches to be repeated, and the purgative medicines to be continued. Five days after this, on feeling

plained to me of pain under his tongue, and on examination there appeared to be an enlargement at about the termination of the submaxillary duct of the right side, and on applying my finger I could distinctly feel a small hard substance. I was at once apprized of the occasion of all the external swelling and violent pain which the man had complained of for so long a time, and, by means of a probe, gently dilating the orifice, and with a small pair of forceps, to my great satisfaction I extracted from the duct a salivary concretion moulded to the shape of the canal, of about three quarters of an inch in length; the moment this plug was removed, his mouth was almost filled with pus of a bloody character, and some clear saliva. He experienced immediate relief, and the swelling was at once reduced from the size of a large hen's egg to a mere trifling enlargement, and it is scarcely necessary to add, that in the course of a few days the man felt himself quite well. There was for the first two or three days a frequent discharge, but after this time he could perceive nothing particular either of the pain or discharge.

I felt much interested in the case, for, on inquiry, I found that he had perceived slight pain and swelling at times for four years previous to this date, and occasionally had had severe pain; and that he scarcely ever sat down to a meal without an almost sudden enlargement of the gland, and particularly so within the last six months, which swelling he could always disperse by pressing on it a short time with his finger.

The sympathy existing between the nerves of smell and taste was, in this case, most beautifully illustrated; for, according to the patient's account, he could never pass a savoury smell without feeling this sudden enlargement, and pain, and he said he had dined but a few days previous to my seeing him from a meal which, to use the man's own words, "always used to make his mouth water," but which in this instance, in consequence of the outlet of the duct being completely closed, had produced so violent a distention of the gland, as at once to set up such a degree of active inflammation, as shortly afterwards led to the discovery of the nature of the disease, and to his relief from suffering.

AUSCULTATION IN VESICAL CALCULI.

To the Editor of THE LANCET.

In the last number of your issue the description of the method intended to facilitate the removal of vesical calculi. A sort of catheter, ap-

pears to be the principle of this invention. Without wishing to engage in any discussion about so trifling a matter, I may, in justice to truth, positively affirm having six years ago applied to Monsieur Charrière of Paris, who made me a long catheter, the handle of which I had topped in the shape of an olive, so as to adapt itself to the ear. I made several experiments on the dead subject with this instrument, and was quite satisfied how easy it was thus to distinguish any and various foreign bodies in the human bladder. I have shown this simple instrument (or spoken of it) to many surgeons in France, in Italy, and in London; nevertheless I am far from accusing Mr. Brookes of taking advantage of the thoughts of another person; and if I am induced to write these lines, it is to corroborate his opinion of the usefulness of such an instrument. The hand of the most talented operator has sometimes deceived his senses. I saw Baron Dupuytren cut for stone where none existed. My friend Professor Roux nobly confesses the same error. I could mention other similar mistakes, but the examples already given are more than enough to prove the utility of using the ear in the examination of the bladder. The hand assisted by the ear will no longer commit such direful errors; nor will patients, operated on for stone by MM. Civiale, Heurteloup, Amussat, &c., be sent away in full security as perfectly cured, with calculi or fragments of stone in their bladder, such cases now being generally known to have occurred. Hoping, Sir, that surgeons will not henceforth neglect this sign in the diagnosis of diseases of the bladder, I have the honour to be, Sir, your obedient servant,

CLAUDICUS TARRAL.

Lawson's Bedford Hotel, Paris,
October 8, 1835.

THE LANCET.

London, Saturday, October 24, 1835.

IN regulating the government of our public, endowed hospitals, no neutral, no middle path between right and wrong, can by any possibility be pursued for any length of time. The circumstances which arise out of their management, must necessarily be productive of good or of evil. Either the inmates of the hospitals must derive advantage from the method of managing those institutions, or their condition must become

absolutely and necessarily deteriorated, from the neglect or want of skill of the medical officers. It is not often that disease will linger in its career. The constitution, on being attacked by an insidious and daring foe, requires all the auxiliary aid which it is in the power of the profession of medicine to afford, in order to remove suffering and ward off the threatened danger. In some cases the malady requires to be watched hourly. In others a visit made daily by the medical attendant, may be sufficient to satisfy the claims of the afflicted. But it is always observed in our public institutions, and even in private practice, that the presence of a physician or a surgeon, who, by his mild and gentle demeanour, and calm and steady firmness in the hour of agony and danger, can ensure the confidence and the favourable opinion of his patient, is enabled to furnish a degree of solace to the mind and feelings of the sufferer, which cannot be derived from any other source,—the inspiring smile, and the hopeful and benign assurance of the skilful medical attendant, often carrying with them an influence which is far superior, as an anodyne, to the effect temporarily resulting from the administration of the most powerful drug.

In the conduct of our hospitals, therefore, every person of ordinary observation and reflection would imagine, *a priori*, that in each of our endowed medical and charitable establishments, there existed an office occupied by a resident medical practitioner of highly-gifted attainments in medicine and surgery, who was fully adequate, on all occasions, to meet the emergencies which must arise in such establishments from the ravages of maladies of a serious character, and by the admission of injuries resulting from accidents of a dangerous and alarming description. Still, however, in this, the thirty-fifth year of the nineteenth century, we find it to be our duty to announce to the members of the medical profession, and to the British public, that the largest, the wealthiest, the most splendid of our endowed

public hospitals, are still destitute of resident surgeons. A fact of this description is not only a stain on the character of the nation, with respect to the general policy of the laws, but it is also a stigma on its reputation for humanity.

It is true, of the minor establishments, we know, full well, that there are persons who are denominated "house-surgeons;" but they are headless lads, who have bought themselves into "office." We know equally well also, that there are medical officers attached to the various hospitals, but amongst these how many individuals are there who disgrace the profession to which they belong, by throwing into their dirty coffers the money which is viciously and basely obtained from aspirants to the office of house-surgeon,—money which is cunningly enticed often from the most inexperienced students, at a horrible sacrifice of the welfare of the patients, and to the utter perversion of every principle of that pure benevolence to the existence of which the hospitals owe their foundation! In *St. Bartholomew's Hospital*, for example, the office of house-surgeon is sold, sold, like an ox or a calf in the neighbouring market! WILLIAM LAWRENCE has been one of the sellers, too, within the last year, and pocketed the cash which he obtained from the purchaser with as little remorse or shame as his brother traffickers on the same day bagged the produce of their cattle sales in the Smithfield pens. Shame, shame, that such practices should be perpetrated in a temple dedicated to the divine purposes of charity! In one institution, as our readers have recently seen,—in the hospital which belongs to the *London University*,—the office of house-surgeon has not been converted into an object of barter, of odious and mercenary barter, but has been made a prize for successful intellectual competition. It has been conferred on To its possessor, therefore, —not the insignificant —scarcely be faithfully

purchase, but those which belong to the well-qualified and experienced members of the profession. But will it be believed that in *Guy's Hospital* there is no house-surgeon, either in name or in substance, and that a like deficiency also exists in the other great hospital of Southwark,—the hospital of *St. Thomas*,—the two establishments commanding, at the same time, pecuniary resources amounting to, if not exceeding, the sum of ONE HUNDRED THOUSAND POUNDS PER ANNUM? Both hospitals, it must at the same time be remembered, are liberally stocked with physicians and surgeons, whose friends and relations in the medical corporations have so contrived affairs that the hospital functionaries are enabled to draw their salaries from the pockets of those medical students who have the misfortune to be the victims of the ticket-and-certificate system. With only one hundred thousand pounds per annum, the funds of those hospitals are too poor to allow adequate salaries to be paid out of them to resident surgeons.

"Ah!" but some of the corrupt and pettifogging tribe will assert, "there is a resident apothecary in each establishment." True enough. So, too, there are resident pestles and mortars, resident mops and resident sponges,—pieces of convenience which are as much at the disposal of the resident apothecary, as the resident apothecary is at the disposal of the non-resident physicians and surgeons. The apothecaries are, in reality, nothing more than pharmacians.* They regulate the dispensing department, and in some instances of *great emergency*, prescribe, perhaps, a dose of rhubarb, or twenty drops of laudanum. But do the apothecaries operate in cases of surgery? Do they dare cut down upon and divide the stricture in cases of

strangulated hernia? Can they find the sheath of an artery, and tie the vessel, in a case of dangerous hemorrhage? Do they attempt even to reduce a dislocated limb,—to adjust the divided ends of a broken bone, or relieve the brain, by means of the trephine or elevator, from the pressure of a piece of bone in a fractured cranium? In short, the apothecaries of our hospitals are the mere servants of the medical officers in matters of dispensing, although they probably go through the formality of an occasional walk along the wards, in order to report any newly-occurring peculiarities in the cases, on the arrival of their masters, who, being particularly industrious and attentive, generally contrive to visit the hospital at irregular hours on two days in each week. Such a system of management one could almost conceive to have been projected by some crafty wily undertaker, who, having engaged to execute by contract the funeral business of the hospital, saw that it would be rendered profitable in proportion to the number of "black jobs" which he should have to execute. That a mode of management so fraught with evil is on the point of terminating for ever, we are well assured, and although this is the best consolation that the mind under the circumstances we have stated can receive, yet an indemnity against future wrong-doing can have no tendency to mitigate the sorrows and sacrifices which the misgovernment of our hospitals has produced during so many successive generations.

The advantages which would necessarily arise from the appointment of a resident surgeon of first-rate abilities to each of our great hospitals, would, in the course of a few years, be incalculable. The sick poor would be efficiently treated, the students would derive perpetual opportunities of improvement from an ample supply of clinical instruction which he does not now possess the means of obtaining, and the facts and observations which practitioners thus favourably circumstanced must be enabled to re-

* We make no attack on the professional character of the gentlemen who hold the office of resident apothecary in these establishments, and we feel pleasure in stating that the apothecary of *Guy's Hospital*, is not inferior to any, but that the business of the hospital is executed with in-

cord, would contribute in a pre-eminent degree to promote the general diffusion and advancement of the thoroughly investigated principles of medical science. As the affairs of our medical institutions are *now* conducted, the responsibilities are so numerous, from their being separated into so many divisions, that there is scarcely a more difficult task to be executed than that of tracing out those links in the chain of circumstances which point to the source of a particular instance of management. Occasionally, indeed often, it happens, that a patient is attended by a physician, a surgeon, an apothecary, a dresser, and a nurse, each undertaking to execute certain duties, but no one acknowledging that the responsibility of the case rests on his own or her shoulders. When Sir ASTLEY COOPER so ably filled the office of surgeon in *Guy's Hospital*, he was so much annoyed by the occasional interference of the physicians with cases of surgery in which he had operated, that he was induced to recalcitrate, and express his great annoyance at the presence of some of the medical officers who were dangling at his heels, and not only interfering with, as that celebrated surgeon has more than once stated in public, but absolutely retarding and preventing the speedy cure of his patients. On one subject of abuse, where there was also a division of the responsibility, arising entirely in consequence of non-responsibility in the proper quarter, the worthy baronet expressed himself thus in the warm and stirring language of indignation and truth. We quote from his 54th Lecture on Surgery in *THE LANCET*, Fourth Edition, page 192, Vol. 2, 1823-24.

"At the present time, however, a surgeon must be either grossly ignorant, or shamefully negligent of the duty which he owes to the character of his profession, and to the common dictates of humanity, if he persists in giving mercury for this disease. Let those persons who suppose that gonorrhœa can be cured by mercury, go round our wards and see whether mercury has any effect on that disease. Look, gentlemen, at 100 patients in our foul wards, many of whom come into the hospital with syphilis and gon-

orrhœa; and many, I am sorry to say, who have only gonorrhœa, but who are invariably carried to those wards. What is the miserable treatment of these patients? You are aware, gentlemen, that I scarcely ever enter the foul wards of *St. Thomas's Hospital*. When a particular case demands my attention, I have the patient removed to the clean ward. I will tell you why I do not enter these wards, gentlemen. I abstain from entering them, *because patients under gonorrhœa are compelled to undergo so infamous a system of treatment that I cannot bear to witness it.* To compel an unfortunate patient to undergo a course of mercury, for a disease which does not require it, is a proceeding which reflects disgrace and dishonour on the character of a medical institution. No consideration shall induce me to repress my feelings on this subject: no authority shall restrain me from giving full expression to those feelings. As long as I continue a surgeon of *Guy's Hospital*, I will endeavour to do my duty; but I care not whether I continue a surgeon of that hospital another day. *I do say that the present treatment of patients under gonorrhœa in these hospitals, by putting them unnecessarily under a course of mercury for five or six weeks, is infamous and disgraceful.* The health of a patient is, perhaps, irremediably destroyed by this treatment, and, after all, not the slightest effect is produced by it on the disease. If he is cured of his gonorrhœa at all, he must be cured by other means. If you go to a patient with gonorrhœa in the foul wards at the end of his course, and ask him how many times he has rubbed in, he will generally answer 'Twenty-eight times.' If you ask whether he is salivated, he will tell you that he spits *three pints a-day*; but ask him whether his gonorrhœa is cured, and he will reply, 'No, I have the disease still upon me.' His disease is not in the slightest degree affected by the mercurial course to which he has been so unpardonably subjected, and it will soon after be necessary to cure him by injections or other means. When so infamous a practice prevails, I cannot satisfy my own feelings by resorting to milk-and-water language; every man of common feeling and honesty is bound to speak out on such occasions."

It is impossible to read this language without entertaining respect for its author. The denouncement of the odious system was honest, bold, and unflinching. In this instance, when *THE LANCET* had existed only about six months, one of the first efforts salting from the existence of the medical press, became possible. During ten years, *THE LANCET* denounced the mercurial

tem of poisoning patients with mercury,—patients whose diseases required not one grain of mercury,—without producing the slightest effect on the ruling authorities of the establishment. At length the denouncement of the shameful abuse was published in this Journal, and along with it some strictures of our own, written in exact accordance with the views of the lecturer, and in less than ten days after the “infamous system” was made public, Sir ASTLEY, at the conclusion of a lecture, thus addressed his class:—

“I believe much good has already resulted from my observations on the abuse of mercury, and I am happy in being enabled to state that the venerable wards of *Guy's Hospital* are about to be opened UNDER NEW AND IMPROVED REGULATIONS. I have spoken to the treasurer (MR. BENJAMIN HARRISON), and I have the satisfaction of stating that the custom of making patients spit three pints a day will no longer be a PART OF THE SYSTEM, but that the venerable wards will be opened under NEW AND IMPROVED AUSPICES.”

Private remonstrance in attempting to correct this horrible abuse of one of the most powerful, and, at the same time, one of the most poisonous of our medicines, was utterly unavailing. Publicity, however, had the effect of shaming the ruling party, or parties, into the adoption of a rational system of treatment. We appeal to all the students who attended *Guy's Hospital* from the year 1816 to the year 1822, and we ask them whether they ever witnessed more distressing scenes than were to be seen in what were called the “foul wards” of that institution. Sufferings of the most dreadful description were caused by the use, the criminal use, of mercury, administered, in fact, for the cure of a local malady over which it had no remedial power, but produced, by its continued employment, often for a month and six weeks together, a train of not less frightful or destructive in its nature than the very worst of the most terrible diseases of the human frame, and with which every medical disease has

often been confounded,* even by discriminating practitioners.

The calamities, therefore, that originated in the abuse which Sir ASTLEY COOPER so feelingly and justly denounced, must, during so many years, have existed to a frightful extent. But where was the RESPONSIBILITY? Oh! it was *divided*. And, in reality, the distinguished complainant and surgeon was not responsible for the treatment of his own patients. There was a gentleman *who ruled over the establishment*. That gentleman was Mr. BENJAMIN HARRISON, and even that important functionary ought to have acted in conjunction with forty-nine associate governors.

Now, we put it to the common sense and the good feeling of the profession, and to the governors of *Guy's Hospital*, not omitting Mr. HARRISON himself, whether so destructive and cruel an abuse, attended with such unfortunate and fatal results, as the one named by Sir ASTLEY COOPER, could have existed for twenty weeks, instead of nearly twenty years, in *Guy's Hospital*, if there had been a resident surgeon in that establishment, and that surgeon had been made responsible for the proper, the scientific treatment of the disease with which the suffering patients were afflicted. Where there exist these mysterious and confounding divisions of responsibility in medical charitable institutions, there are always observable in them evidences of neglect or mal-treatment. Few or no facts are collected in them that may be added to the existing stores of medical knowledge; instances of proffered aid are regarded as so many uncalled-for interferences, professional jealousies are excited, and as each practitioner seems to feel that the credit of a cure cannot be the reward of his exertions, neither will the cause of death be attributed to his supineness or his want of ability.

But let us turn our attention from the hospitals which are receptacles for the sick poor, to the metropolitan institution of

CHRIST'S HOSPITAL, the maintenance of the health of whose inmates is regarded as an object of the greatest importance with respect to the high objects of moral and intellectual attainment. In this establishment one disease has continued its destructive ravages for a long series of years, not only uncured, but almost unrelieved or unchecked. In this single instance we observe all the mischiefs which arise out of injudicious appointments, in the first instance; and, secondly, from the inpolitic division of responsibility amongst the medical officers. Since the year 1820, Dr. ROBERTS, Dr. CLEMENT HUE, Mr. ABERNETHY, Mr. LLOYD, and Mr. FIELD, who has lately resigned the office of apothecary, have been the medical attendants of the children; and, in addition, there was, on one or two occasions, a visiting medical committee appointed, which embraced Mr. LAWRENCE, Mr. BRODIE, and others, the personal friends, and, for the most part, the colleagues, of the officers of the establishment. Who, then, is responsible for the ravages which the ringworm has committed in this establishment,—for the sufferings which the poor children have endured,—for the bodily restraints to which they have been subjected,—for the imperfect education of which they have been the victims? It will be answered, that the whole of the medical officers are responsible. Ay! When it is thus divided, the portion which each has to bear presses so lightly that it is scarcely felt to be an inconvenience, and even that portion is blown away by the mere breath of either officer who alleges "that he could not cure the patients because the medical management of the children was not placed entirely under his control,"—a statement which is rendered perfectly justifiable by the circumstances connected with the duties of each of the medical officers. Disastrous enough have been the consequences. The UNDYING RINGWORM has pursued its course; the children have long been kept on a most unwholesome diet; the

unfortunate boys have been tortured by the endless application of plasters and unguents to their scalps: and, what is still worse, the mental soil has, in numberless instances, been left entirely unimproved and uncultivated. These facts are most lamentable, but there is one which is also most extraordinary. The labours, the discoveries, the observations, of the medical officers of *Christ's Hospital* have not contributed one solitary page of information to our stock of knowledge on the subject of ringworm. So far as the labours of those officers are concerned, the members of the medical profession in this country are just as wise on the nature and treatment of ringworm, as they were on the first day that that malady made its appearance in the institution. We say, therefore, fearlessly and unhesitatingly, that if a succession of resident surgeons,—that is, supposing the first had failed or died,—had been appointed, no such omissions or results as those which we have stated, could have been observed or recorded.

With these views and impressions operating on our feelings, we look forward with the utmost anxiety and apprehension as to what may be the rules of management for the medical officers, after the coming election of a resident surgeon to *Christ's Hospital* has terminated. It is of no use to appoint a competent practitioner, and then bind and manacle him. His mind must be left at liberty to act with the utmost freedom from the exercise of any controlling influence on the part of those medical officers who now belong to the establishment, and for whose talents and zeal the "undying worm" has proved itself to be more than a match.

This journal is published nominally every Saturday; but, in reality, it is in the hands of our metropolitan readers every day on Friday. The election of a resident surgeon to *Christ's Hospital* has taken place on Friday the 23rd of the month, and the opportunity, therefore,

last words to the governors on the subject of appointing resident surgeons to our hospitals generally, and of the mischances that have happened, particularly from a division of medical responsibilities, in the institution over which we know it is their desire to exert an efficient salutary control. The candidates for the vacant office are about twenty in number, that is, if all can be called "candidates" who have issued letters of solicitation, without entertaining the hope of obtaining a single vote. From what we have been enabled to observe, we may state that the actual candidates may be divided into two portions; the one party having the fullest and most substantial claims to the confidence of the governors; the other part consisting of persons who have no title to the respect of the electors, although, as regards *confidence*, it is quite evident that they possess enough of it—in themselves. The candidates placed in the two divisions stand thus,—Mr. PLUMBE on one side,—a score of opponents on the other. Here, then, is a contrast presented by the claimants for the office, and it would be quite useless to institute a comparison, for there is in reality nothing to compare, unless the shadow be classed with the substance,—unless the inexperience of youth can be made to maintain a parallel with the matured knowledge of a twenty-years' assiduous devotion to the labours of an arduous profession. Some of the candidates, we understand, have been educated at *St. Bartholomew's Hospital*, but we will not do the governors the injustice to believe that even a thought will be entertained of taking another gentleman from that school to place him in the office of medical attendant in *Christ's Hospital*. No such folly, such pernicious folly, can be committed by rational and benevolent men. The teachers of *St. Bartholomew's Hospital* may be men of excellent and of first-rate ability in the profession, but the many years has that they are in-

capable of curing the disease called "ring-worm,"—that the suffering children of *Christ's Hospital* have received from the hands of Dr. ROBERTS, Dr. HUE, Mr. ABERNETHY, and Mr. EUSEBIUS LLOYD, (the present consulting surgeon of *Christ's Hospital*), who all have been, and still are, lecturers and practitioners in *St. Bartholomew's Hospital*, little or no relief from the persecuting malady with which they are afflicted. All of these gentlemen have held office, have been consulted, or are still holding office, in *Christ's Hospital*, and their efforts in the attempt to cure the heads of the afflicted children, have been utterly and signally unavailing. The masters, the *instructors* of youth, have failed, and shall it be said that the apprentices, the *instructed*, shall be selected, in the hope that inexperienced youth can accomplish, in the treatment of disease, obstacles which are not to be surmounted by the ripened knowledge of experience and age? No such selection can be made by the governors. A choice of that kind would, in reality, be little less than a solemn mockery of the complaints which have been so loudly made by the parents and guardians of the distressed and tortured children. There may be amongst the governors two or three mischief-makers who may be swayed in their choice by the interests of party, rather than by the dictates of reason, and whose love of intrigue may be superior to that of works of benevolence; but confidently assured are we that an overwhelming majority of the governors will be influenced in the selection of a candidate by an earnest, noble, and generous desire to spare the interesting objects of their solicitude every torment which can be averted by the judicious exercise of medical skill. No consideration of a less rational or humane tendency can by any possibility determine the choice which is about to be made by a large body of independent English gentlemen. They are called upon to act as parents on this occasion, for the children are placed entirely under their guardianship. On reflection they must

perceive that it is their paramount duty to get rid of the scourge which has so long pestered hundreds of the scholars, and in furtherance of that duty we now once more earnestly express a hope, THAT THE GOVERNORS WILL NOT BE INDUCED TO ELECT THE RESIDENT MEDICAL OFFICER FOR A LONGER PERIOD THAN ONE YEAR. Whatever may be the entreaties of the candidates, or the petitions of their friends, THIS LIMIT, relative to the time of holding the office, SHOULD BE RESOLUTELY FIXED, and not departed from under any pretence whatever. At the end of the year, if the state of the children do not indicate that a confirmed progress towards the improvement of their health has been made, the surgeon who has been allowed a twelvemonth's trial, should instantly give place to a successor in his office. In acting with decision and promptitude, the governors discharge no more than their duty towards the children; whereas if their conduct be marked by the slightest evidence of snipiness in matters of such vast importance as the health and education of the pupils, they cannot justly be excused from an accusation of culpability.

In contending for the superior claims of Mr. PLUMBE, we trust that the character of this Journal will fairly permit us to refrain from remarking that we are influenced by no partial or unworthy motive. He has proved by his published works, by his success in the important medical offices which he has already held (those of senior surgeon to the St. Giles's Infirmary, and of senior surgeon, for many years, to the Metropolitan Infirmary for Children), that he is capable of maintaining a first place in the rank of medical practitioners, and that in his knowledge of the nature and treatment of diseases of the skin, his superior is not to be found amongst the physicians and surgeons of this metropolis. His claims to the favourable opinion of the governors are founded on his talents and experience. His title to the support and recommendation of this Journal has an other foundation

The duties of the Governors, with regard to the medical care of the children, must not terminate with the appointment of PLUMBE. After he has been installed in his office, that gentleman must be left free to act. He must not be hand-bound. He should be entrusted without restraint with the care of the health of the children, which would necessarily place their medical and dictetary management under his control. With such an arrangement there would be no *shifting of responsibility*. If the mode of treatment should fail, the Governors will at once be enabled to trace the failure to its right source, and other professional aid must be sought for and obtained. It is high time that all forbearance or dalliance with such an insidious and destructive foe as the ring-worm should terminate. From the number of communications which we have received on the subject of this election, we know that the parents and guardians of the children are awaiting, with the most intense anxiety, the result of the contest. A respectful and generous reliance is bestowed by their relatives on the judgment and benevolence of the Governors; and as for the afflicted children, their hands are raised towards their benefactors in piteous mood, expressively, though silently, hoping that the hour of redemption from their prolonged sufferings is at last drawing near. They who can remain unmoved in the presence of such a scene, and who can suffer their judgment or their motives to induce them to vote for the candidate whom they do not believe to be the best qualified and the most capable to protect the scholars from the further destructive ravages of the disease, must have their feelings steeled against all the finer sympathies of human nature. We hope and believe that persons of this description are not to be found amongst the benevolent Governors of *Christ's Hospital*.

A letter appeared
Thursday, October
"Christ's Hospital"

"ROBERT BENNINGTON." In this letter the writer observes,— "In the London establishment, the disorders affecting the scalp, formerly so troublesome, have, I understand, disappeared." *Disappeared!* Why not say *cured*, if such be the fact? But is it not strange that Mr. BENNINGTON, the medical attendant of the branch establishment at Hertford, should undertake to give an account of the state of *Christ's Hospital* in London? The time has been conveniently chosen for writing this delusive canvassing letter; but we feel confident that the Governors are not to be deceived by any such efforts, and that on the day of election they will conscientiously and honourably record their votes in favour of that man who by his researches, his experience, and the devotion of a great portion of his professional life to the consideration of the diseases of the skin, and who, by his discriminating and prudent recommendation to the Special Committee of *Christ's Hospital*, has proved that he is pre-eminently qualified to occupy the office of resident surgeon in that great national establishment.

It is a curious fact that Mr. JEAFFRESON, of Framlingham, in a letter which was published in *THE LANCET* of March the 14th, 1835, page 872, while speaking of the qualifications of Mr. BENNINGTON, who had been his apprentice, refers, in proof of the first of those qualifications, to the fact that *during his apprenticeship* Mr. BENNINGTON had "*read the works of PLUMBE on the history and treatment of ringworm.*" The governors of *Christ's Hospital* have now the opportunity of choosing between the PRECEPTOR and the PUPIL. To suppose, for one moment, that they would prefer the latter to the former, while yet Mr. PLUMBE is scarcely forty years of age, and therefore in the prime of life, would be anticipating that he would display a perverseness which would indicate to the public that all lay interference in the elections of our

public institutions should cease and be abolished for ever.

THE contest for the office of surgeon in the parish of St. Clement Danes, after the votes had been recorded by ballot during three days, terminated on Wednesday last, in the election of Mr. COSGREAVE, by a majority of 103 votes over his opponent. We do not blame Mr. DUNN for having offered himself as a candidate on this occasion, but we condemn the principle by the advocacy of which he endeavoured to sustain his claims to the confidence of the rate-payers. On every account we rejoice in the election of Mr. COSGREAVE, because we are satisfied that he has discharged his duty to the poor with humanity, industry, and skill; and better proof of this assertion cannot be offered than the fact that although our office is in the centre of the parish, and situated within two hundred yards of the workhouse, not a single complaint against the parochial surgeon has been made to us in the course of the nine years during which Mr. COSGREAVE has filled the situation. If such a man is to be rejected because another person thinks that *he* ought to occupy the post, there would be an end to the respectability of the profession, to the humane treatment of the poor, and to the stability of all useful and efficient reforms.

WE regret that we have not space in the present *LANCET* which will allow of our offering a few additional words to the "recognised" lecturers. They contend that we are unjust in our remarks, and that the existing system is not one of robbery and delusion. We must appeal from their verbal decision to the experience and feelings of the pupils. By some of the lecturers our opinions and views have been wholly misrepresented. We thank them for their falsehoods.

The Anatomy of the Regions interested in the Surgical Operations performed upon the Human Body, &c. In a series of Engraved Plates, on India Paper, the size of Life. By J. LEBAUDY, M.D. London: Bailliere, 1835; 4to, pp. 32.

WE cannot consider the present volume (which is priced at the sum of one pound four shillings), notwithstanding the freshness of its title and appearance in some parts, to be any other than the atlas of the *Journal des Connaissances Medico-Chirurgicales*, which is sold at the bureau of the journal, Rue de l'Ecole de Medecine, next door to the Hotel Herisson, for the much more modest sum of six francs. M. Lebaudy is an excellent artist himself, and his plates have been designed and engraved with much accuracy by some of the best artists in Paris. We have, therefore, no objection to make against the surgical value of the work, but must protest against the high price which has been set on it in an English dress. We know that the *Journal des Connaissances* owes the immense circulation which it has obtained in a short time, to the cheap and inadequate price at which it was originally published,—five shillings per annum. It is, therefore, not very unlike an imposition to take the atlas of that journal, paste the words "Published in London and Paris by J. B. Bailliere," over the real title of the plate, and sell it, with thirty-two pages of description, at such an unconscionable increase on the original cost. We should certainly advise a reduction in this respect, and also in another, that of the number of the plates, for instance, plate 18, which, though suitable enough in the journal that originally contained it, is misplaced in a work on surgical anatomy.

On Blood-letting.—An Account of the Curative Effects of the Abstraction of Blood; with Rules for employing both Local and General Blood-letting in the Treatment of Diseases. By JAMES WARDROP, M.D., Surgeon to the late King, &c. London: Bailliere. 1835. post 8vo. pp. 148.

THE lectures on the above subject, which were made public some months since by their eminent and experienced author in the pages of *THE LANCET*, elicited expressions of admiration from the most intelligent medical practitioners in all parts of

the country, not only in consequence of the novelty of many of the doctrines which were then enforced by Mr. Wardrop, but also from the philosophical views and the strictly physiological and pathological principles on which his opinions were founded. The extensive practice which naturally attends the professional fame of an able and accomplished surgeon, speedily affords him gratifying opportunities of learning the extent of favour with which his published doctrines, far and wide, have been received. Prompted, therefore, in the present instance, by an assurance of the feelings of interest which his labours in diffusing a correct knowledge of the principles of blood-letting have excited, the author has here combined, in a series of uninterrupted pages, all that he had to communicate on the subject, with something in addition, as we learn from the preface to the edition before us, with a quotation from which we shall be content in noticing the volume, for further extract would be useless on an occasion in which the author has simply strengthened the arguments, not enlarged the opinions, he had previously employed:—

"Embracing some of the most important subjects of discussion in medical science, the following observations were not submitted to the profession without the exercise of much care and deliberation; and the favourable reception which they obtained has induced the author to collect and publish them in the present form. In accomplishing this labour, however, he has not failed to use his best endeavours to render the work more comprehensive, by dwelling at greater length on some points, and by giving additional cases illustrative of several interesting topics.—Charles Street, St. James's Square, October, 1835."

The volume is most conveniently indexed by side-notes in each page.

A Practical Treatise on the Diseases of the Uterus and its Appendages &c. By Madame BOIVIN and A. DUCIS. Translated, with copious notes, by G. O. HENNING, &c. London: Sherwood, 1834; 8vo. pp. 559, plates.

THE original of this translation

for several years before the

and its value is full

Boivin was a woman

La Chapelle, and in

composition of her work she has been ably assisted by Monsieur La Duges of Montpellier, who, by-the-by, composed a great part of the late Madame La Chapelle's work, also. A good standard treatise on the diseases of females was always a desideratum, not only in this country, but in most of the continental states; indeed we cannot say that the want is yet satisfied, unless we allow, with some physiologist, whose name we forget, that "the uterus makes the woman." Were the latter proposition true, Madame Boivin's work would be almost perfect, for nothing can exceed in fidelity her description of the natural structure of the uterus, and the various morbid changes to which that organ is liable. However, as she professed to confine her attention to diseases of the uterus, we cannot reproach her for limiting the range of her investigations.

We are relieved from the necessity of noticing the present translation in detail, by the copious extracts which have been already long given from the original. We shall therefore content ourselves with again repeating that the work of Madame Boivin and Monsieur Duges on the diseases of the uterus is indispensable to the library of every practitioner; and that Mr. Hemming has shown a sound discrimination in rendering it into our own language for the advantage of those who are not familiar with the original. We should mention that the work contains forty-one plates, from drawings on stone, and executed with sufficient accuracy. It would perhaps have been better had the plates been kept separate from the letterpress, as in the original work, and thus afforded English readers an opportunity of purchasing either separately.

Jardine's Naturalist's Library Entomology.
Vol. III. *British Butterflies.* By JAMES DUNCAN, M.W.S. Edinburgh: Lizzars. London: Hignley. 1835. pp. 216.

MR. HIGGLEY has issued two more volumes of his very interesting scientific work,—the second devoted to the class of pigeons, (entitled) to the British Pigeons, which require to be seen, and it is ensured to be a work which those

are published. Nothing so cheap in the way of information has yet come from the press. Each plate of the seventy in these two volumes is coloured, and with remarkable fidelity. An exception exists here and there in the portraiture perhaps. In the "wood pigeon," for instance, we detect one, but the faults altogether are very rare. A memoir of Werner is prefixed to the volume on Butterflies. The selection of the biography of this philosopher to enlarge the bulk of a work on butterflies is somewhat odd. The man of rocks and metals seems to preside heavily over the memorials of such feather-weight objects. Werner, however, had one thing in common with as great a man in the latter way. As the enthusiasm of the latter led him to believe that butterflies carried language on their wings,—for he desired his mistress, when they crossed her path, to read thereon words of affection from himself,—so Werner fancied "that stones could speak," and demanded from them the history of the whole world. Such, indeed, was his notion of the science, that he even, says Cuvier, "endeavoured to trace the laws of military art to those of geology, and if his account was to be received, every general should have commenced his career by studying for some time at Freyburg," where Werner held the post of professor, and inspector of the cabinets. It is only these excessive enthusiasts who achieve the highest results in science.

There is a very curious fact in the history of Werner, which is worthy of being noted among men of science. He wasted no time over pens and ink. He constructed no manuscripts for the diffusion of his fame. He left the simple facts which he discovered to work their own way, as they could, into general circulation. It was enough for him to detect them, and divulge their existence by word of mouth. He would not write. He hated the scribbling art with an intensity unmatched,—with an abhorrence so great, that it is hardly unreasonable to ask if he knew "the way," while the curious may ask with laudable eagerness to see his autograph, if he ever left one.

The following extract from the *Eloge*, pronounced by Baron Cuvier before the University of France, will be read with interest, not only from the singular details which it contains relative to this circum-

stance, but from other characteristic acts which are calculated to engage the attention of the readers of a work of tuition. Whatever is not new in this account is worth reviving:—

“Strangers who happened to visit Werner at Freyberg, and expected to enter into conversation with a mineralogist only, were surprised at his continual discussions on tactics, politics, and medicine. They were sometimes tempted to regard them as allied to the reveries of a maniac. Indeed, we may admit that there must have been something of exaggeration in generalizing to such an extent the relations of a single object; but the disciples of Werner hurried with enthusiasm upon a field of inquiry which he described to them as so vast and fruitful as to embrace all these topics. A mineralogy which was purely mineralogical, would perhaps have disgusted many of them; but they devoted themselves with ardour to a mineralogy which seemed to present them with a key to all nature: and even although, on a final analysis, there might only remain to them the foundation of the science, would they not still have reason to rejoice at the pleasing illusions which had been the means of leading them thither? Some individuals who have since risen to the first rank among the mineralogists of Germany, had wished to hear him, only for the purpose of obtaining a summary knowledge of mineralogy; but having once listened to him, that science became the profession of their lives. It is to this irresistible influence that the scientific world has been indebted for those laborious observers who have removed from the globe the last veil that concealed her mysteries. Karsten and Wiedman in the cabinet—Humboldt, Von Buch, Daubuisson, Hermann, and Freylenben, on the Cordilleras, amidst the flames of Etna, in the deserts of Siberia, in the mines of Saxony and Potosi—have been led on by the spirit of their master. They always ascribed to him the honours that resulted from their labours; and it might be said of him, what could formerly be said with truth of Linnaeus only, that nature was every where interrogated in his name.

“Few masters have enjoyed in the same degree the pure and unreserved gratitude of their scholars; but no one, perhaps, had ever so much deserved it by his paternal regard for them. There was no sacrifice which he would not make for his pupils. His time and strength were at their service; and if he knew that any of them were in temporary

need, his purse supplied their wants. When his audience became too numerous for each to see conveniently the objects which he exhibited, he divided the students and repeated the lecture. His door was at all times open to them; he took his meals usually with some of them, as if he wished that no opportunity should be lost for their instruction. Such a master might well entrust the care of his reputation to his scholars; and it is, in fact, by them that it has been established. In this point, also, resembling Socrates, to whom he has been compared in so many other respects, nothing can be known of his views but from the notes that have been taken of his lectures. Whether it was that he became satisfied with the ascendancy which he acquired by his powers of speaking, or that the vivacity of his imagination could not submit to the restraint and tediousness of writing, it was only with the greatest difficulty that he was induced to prepare for the press one or two pamphlets and a few articles for the journals, though he engaged in oral discussions as readily as could be wished, and for hours together would utter the boldest and best-connected ideas. Nothing, however, could make him take up a pen. His antipathy for the mechanical act of writing, was rendered amusing by its very excess. His letters are extremely few. The tenderest friendship, the most profound esteem, could scarcely extort one from him; and at last, in order that he might not reproach himself for his want of politeness, he ceased to open such letters as were sent to him. One author, who was desirous to have the opinion of many scientific men respecting a voluminous work, circulated his manuscript among them. During its progress the packet was lost. After a thousand researches, it was at last disinterred from under a hundred others in the house of Werner. To carry this matter to the extremity, he did not even reply to the French Academy when it placed him on the list of its eight foreign associates, which is adorned with all the great names of which Europe has been able to boast for more than a century. Perhaps he did not even know that this honour had been conferred on him, unless he chanced to learn it from some amanuensis. This insurmountable antipathy to writing caused him to infringe the laws of etiquette, which next to his studies affected him most. In everything else he is said to have observed the slightest courtesies of social life with as much punctuality as he attended to the varieties of minerals. His little eccentricities, at which he was the first to smile, in no respect unpleasant in their nature, whatever is most elegant and amiable in disposition, and in the accommodation of his scholars, was ever ready to be shown.

by attending to his foibles. But these peculiarities posterity has to lament, as they have thereby been deprived of valuable works, which no one else for a long time can execute so well. It is said that the first sheet of his great work on mineralogy was sent to press, but that he could not undergo the fatigue of correcting the proofs. His whole life was thus spent in ignorance of all that was going on at a distance, without reading the journals of literature, and without even ascertaining whether envy had occasionally made him the object of her attack. His life might have been expected to be prolonged for a considerable time; for of all the methods which he had studied, that of taking care of his own health had not occupied him least. But the misfortunes of Saxony escaped his foresight, and destroyed his peace, and his resulting anxiety produced a complication of diseases, to which no cure could administer a remedy. He died in the arms of his sister, on the 30th of June 1817, aged 67, at Dresden, whither he had gone in the hope of some alleviation of his sufferings."

The Clinique Médicale, or Reports of Medical Cases. By G. ANDRAL, Professor to the Faculty of Medicine, &c. Condensed and translated by D. SPILLAN, M.D., &c. London. Renshaw. 1835. 8vo. Parts I. and II.

WE recommend this translation as a production which presents two advantages that are not often found in combination in medical works. In the first place the original (which, as we have before said, is too well known to require comment) is the best system of medical pathology extant; and in the second, the translation, which seems to be executed with accuracy and care, is moderate in price. Generally speaking, the English translations of foreign works are published at unreasonable prices. Their circulation is thus necessarily limited, and the good example of many excellent continental works prevented from exercising the influence on medical literature and practice which it is desirable that it should obtain. The price of this translation will, when it is completed, hardly be higher than

of the original, and he must be a hardy man who will contend that a translation is more for his labours than the original translated.

produced with great accuracy, and is well economised.

Observations on the Principal Medical Institutions and Practice of France, Italy, and Germany, &c. With an Appendix on Animal Magnetism and Homeopathy. By EDWIN LEE, M.R.C.S., formerly House-Surgeon to St. George's Hospital. London. Churchill. 1835. 8vo. pp. 216.

THE contents of this volume are justly described in the preface as presenting "an impartial and not inaccurate sketch of the actual state of medical and surgical practice in France and Italy," with some "notes on German Institutions, less copious, but calculated to convey some idea of the state of practice in that country."* The author might have given other qualities to his sketch with advantage, because the great bulk of his matter is not new to this country; but he does not seem to be a gentleman of much originality or expansiveness of view, or one who is likely to handle an old subject, or newly arrange the points of a stale topic, in a more vigorous or attractive manner than his predecessors, and we willingly excuse his abstinence from the attempt. He would certainly have failed in the effort. His dedication, however, of a volume devoted to an exposition of the free medical institutions of the continent, to one of the most narrow-minded and illiberal functionaries of the close hospitals and colleges of Great Britain, was a mistake of which he should not have been guilty, and certifies very early in the book more respecting the deficiencies in its character than there is any occasion to denote here. Even as it is, Mr. Keate must have received his copy of the volume as a diseased child receives into its unwilling hand a cup of detested rhubarb. But impartiality and accuracy are excellent qualities, and having said thus much respecting the absentee virtues, we express contentment with the labours of Mr. Lee in that respect. His volume will prove useful to medical students who visit the continent, and afford them a fair extent of introductory knowledge respecting the institutions which supply the means of professional learning in the quarters specified. Scattered through its pages we find

* Mr. Lee's grammar cannot be much praised. How many languages are studied by Englishmen in preference to their own? "German institutions" do not constitute a "country." Such blunders are frequently made.

was impossible to judge. In confirmation of this, he alluded to the case of a girl who had been received into *Guy's Hospital*, while the catamenia were present, and which were arrested suddenly by the affusion of cold water, followed immediately by a severe attack of pleurisy, attended with numbness and œdema of the inferior extremities; but so soon as the uterine disturbance was corrected, the pleurisy and other symptoms induced by the arrest immediately disappeared.

Dr. JOHNSON adverted to the fall which the patient had received, and said he had requested the advice of an eminent physician-accoucheur and pathologist of this metropolis, whose letter in reply to that of Dr. Johnson was read, but it simply and briefly attributed the sufferings to spinal disease.

The PRESIDENT (by the special request of Dr. Johnson) gave his opinion on the treatment; he suggested that perfect rest for months should be enjoined, and that a nourishing diet should be allowed, and anodyne injections used; but during the time the catamenia were present, he would strongly recommend that the patient should move about, as a sluggishness of the uterine functions at that time, he had found, greatly contributed to increase the debility. He could easily conceive why the stimulating preparations of iron had not proved beneficial. These he never prescribed under similar circumstances, for he had found that such stimulants naturally increased the irritation, and thereby kept up the pain, suffering, and disturbance. The same objection, however, was not to be urged against the diffusible stimuli, and from the carbonate of ammonia, rendered palatable to the patient, he had derived in his practice great benefit as a stimulant.

Dr. RYAN, in addition to this treatment, recommended small doses of strychnia, and the introduction of metallic sounds into the uterus; in the use of which instruments he had seen much benefit derived when cautiously introduced into the uterus, commencing with small-sized bougies, and gradually increasing them; for while the patients were suffering from dysmenorrhœa, he had ascertained by examination at the time, that the parts were much contracted.

Mr. CLARKE observed, that whatever merit attached to this plan, was due to Dr. Macintosh, who introduced the practice.

Mr. COSTELLO remarked that this formed one of the improved plans of treating urethral diseases, which he hoped shortly to lay before the Society.

Mr. STRERRON then exhibited to the Society some diseased preparations of fungus hæmatodes, attacking different structures in the same individual, and the Society shortly afterwards adjourned.

LONDON UNIVERSITY MEDICAL SOCIETY.

Oct. 16, 1835, Mr. CHIFFENDALE, President.

MOLLITIES OSSUM.

(From a Correspondent.) — A paper on mollities ossium was this evening read to the Society by Mr. PIPER, and followed by an animated discussion, in the course of which several theories on the pathology of the disease were advanced. Mr. HAYMES thought that proof that phosphoric acid was superabundant in the system, had been afforded by analyses of the bones of persons who had died from this disease, and that their insoluble phosphate became by this means converted into a soluble superphosphate, which was thus, with much greater facility, removed, by the absorbents diminishing, more or less rapidly, the quantities of earthy material. Mr. PACKMAN advanced an opinion that the disease arose in consequence of deteriorated function of the peristœum, its arteries having lost their healthy secreting power, while the absorbents still continued to remove the portions of earthy matter that had already been deposited. Mr. BRENT endeavoured to follow up this view, and supposed the *reason* of the peristœum being unable to secrete a healthy deposit (in cases where immense quantities of common salt had been habitually swallowed by the patients, as has been said to have frequently been their custom) to be either the result of sympathy with the stomach and other organs of digestion, so greatly debilitated by the salt, or else that the salt itself soon became absorbed into the circulating fluid, and re-acting upon the phosphate there, as well as on that contained in the osseous structures, produced two partially soluble salts, the phosphate of soda and the muriate of lime, which were immediately taken up by the vessels. He added that the disease might, on the other hand, arise from deficient action of the kidney, that organ becoming unable properly to separate the salts from the blood, which, by accumulation, would have the tendency of giving rise to the soluble salts. The phosphoric urine, he argued, was a sufficient proof that the urinary organs were disturbed. Messrs. KANE, and other gentlemen, who were present, were of opinion that the subject, which contained many interesting points, until the period of the meeting.

NORTH LONDON HOSPITAL.

CARIES OF THE OS CALCIS.

AMELIA CALLOWAY, aged 17, was admitted, May 12, under the care of Mr. COOPER. About three years ago a swelling appeared under the ankle of the right leg on its internal side. Sometimes it was very painful, but she continued to move about until the week previous to her admission. Some time last March the swelling broke. She had experienced a little relief at a dispensary, until a short time before her admission, when she got much worse, and her general health suffered considerably.

14. Pain so violent in the ankle that she cannot sleep; poultices have been constantly applied to the swelling.

June 20. She has been more free from pain since the last report, but has complained occasionally of sleepless nights. She has been taking small quantities of iodine, which, depriving her of her appetite, was discontinued, and sulphate of quinine, with infusion of roses, was given instead. On introducing the probe into the sinus, it is felt to penetrate deeply into the cancellous structure of the os calcis.

Aug. 1. Mr. COOPER being out of town, Mr. LISTON to-day removed a portion of the os calcis with a small trephine, scooping out a portion of the cancellous structure of the bone. The part was stopped with lint, and a poultice was applied.

Sept. 21. A small piece of bone exfoliated a month ago, since which time the wound has been gradually healing, and is now nearly closed.

Mr. LISTON remarked on this case, that the disease was most frequent in the heads of bones and in short spongy bones. It also sometimes occurred in the cancelli and shaft, and in flat bones, between the tables. The cause of the disease was external injury and incited vascular action; suppuration in the cancellated texture frequently following very slight incited action in persons of a scrofulous habit. Great suffering generally is experienced during the progress of an acute abscess to the surface. An enlargement usually ensues from the addition of new bone, which is arranged in nodules on the outer table, and sometimes extends to the bones which are articulated with the bone that was diseased. There is one or more cloaca leading to the ulcerated surface, the discharge proceeding from which is purulent and fetid. The soft parts around the bone are condensed so as sometimes to form a bony shell. The os calcis is the bone most frequently affected with this disease, probably on account of its position. This disease is not infrequently met with in various points; it

sometimes commences in the bursa, sometimes in the substance of the bone. It varies much in extent and degree. The softening and disease are not always limited to one bone, but affect the synovial apparatus between the astragalus and the other bones. The prognosis is various, according to the extent of the disease.

In treating this complaint, Mr. LISTON remarked in continuation, that it is necessary to remove partially or entirely the part diseased, or to bring on such a change of action as will throw it off. The first object may be accomplished by trephining, as in the case in question, by scoops, saws, or forceps; the second can be effected by the potential cautery, the red oxide of mercury being generally preferred by the lecturer. Mr. LISTON exhibited several specimens and drawings from various cases, showing the different kinds of the disease.

DISTRESSING SICKNESS CURED BY CREOSOTE.

Dr. ELLIOTSON, in a late lecture, related the following case, which shortly since occurred in his private practice. Mrs. P., a lady, residing near town, when apparently recovering from an attack of sore throat, was seized with incessant retching and vomiting, accompanied with debility and depression, both of mind and body. This distressing state continued for a week, during which period no food of any description was retained in the stomach. There was no pain on pressure, and no other inflammatory symptom. Wine, brandy, and even soda water, were all immediately ejected. The pulse was extremely feeble, and almost imperceptible, and she had frequent fainting fits. Two-grain doses of hydrocyanic acid, though repeatedly administered, had an effect in stopping the vomiting. She was supported during the week by nutritive glysters containing white of egg and milk. It was after a week, during which the above symptoms continued undiminished, that Dr. ELLIOTSON was requested to see the patient. He ordered her two minims of creosote, to be given every two hours, and increased if the sickness continued, but to be diminished if it ceased. The first dose was thrown up, but a second, administered immediately after, remained on the stomach. The next dose, given in two hours, came up. Another was administered and retained. The vomiting had entirely ceased on the next day, without any increase having been made in the dose of the medicine, which was therefore now diminished in quantity, and, shortly after, entirely discontinued. The patient rapidly recovered, and is now in good health. Dr. ELLIOTSON has had repeated opportunities (besides the cases already published in THE LANCET) of trying the effects of creosote in vomiting, but

as the details would present mere repetitions, we refrain from giving them. The medicine has certainly sustained in his hands a high character. The judicious directions, however, which Mr. TAYLOR affixed to the cases published by that gentleman in a recent Number of THE LANCET, should be carefully observed by those who make trial of the creosote.

LITHOTOMY.

Thomas Smith, aged 6½ years, was admitted, Oct. 15, under the care of Mr. LISTON. He has manifested symptoms of stone from infancy, the most marked symptoms being a pulling at the prepuce, and violent pain while making water, which dribbles from him, soiling his clothes. During the time of micturition he is very restless, tossing about in every direction. These symptoms very much increased as he became older. Mr. LISTON having sounded him and detected a stone, the boy's friends being anxious that the operation should be performed immediately, he was cut on the day of admission. The boy being held between the knees of an assistant, a small curved staff, with a groove a little on one side, was introduced, and held firmly by another assistant, towards the arch of the pubis. The incisions were made in the usual way with a common dissecting scalpel, and the bladder was reached. The staff was then withdrawn, and the stone extracted with a small pair of forceps in forty seconds from the first incision. On the 21st he was doing exceedingly well.

OPERATION FOR CATARACT.

Margaret Lake, aged between seventy and eighty, presented herself at the hospital on the 15th of October with cataract of both eyes. Mr. LISTON operated on the right eye, the pupil being previously dilated, by dropping in a little solution of extract of belladonna. Having covered the left eye with a bandage, he made steady the right one with his left hand (Mr. L. frequently impresses on the pupils the necessity of practising with both hands alike, as, for instance, in this operation on the left eye, in cutting for fistula ani on the right side, and various other operations), he then introduced the cataract-needle with his right hand, about a line or so from the junction of the sclerotic coat with the cornea, and reclined the cataract, gently disentangled it, and withdrew it cautiously. The eyelids were then closed, and a small piece of lint dipped in cold water, and a bandage, were applied to the eye. Mr. LISTON remarked, that in the generality of cases this was the preferable operation.

ST. BARTHOLOMEW'S HOSPITAL.

OSTEO-SARCOMATOUS TUMOUR OF THE LOWER JAW — OPERATION — EXCISION OF THE BONE.

On Saturday, Oct. 17, an interesting-looking girl, of about sixteen years of age, was led blindfolded into the operating theatre. On being secured on the table, the disease evinced itself by a tumefaction in the situation of the left side of the under jaw-bone. Mr. STANLEY intended, in accordance with the joint approval of his colleagues, to remove the morbid growth by extirpation of the diseased bone. He commenced by an incision extending from the symphysis of the chin to the articulation of the jaw, on the left side, in a curved direction, according with that of the shaft of the bone. On reflecting the integument, the external facial artery was wounded. This was secured by Mr. LAWRENCE, who assisted the operator, who then proceeded to dissect cautiously through the buccinator muscle and the coverings of the maxillary bone, about an inch inferior to the duct of the parotid gland; in accomplishing this, several small branches of the external maxillary artery were divided, and successively secured by the assistant. After carefully exposing the whole shaft of the bone to above its angle, Mr. STANLEY separated the muscles which were attached to its inferior margin as well as its internal surface, by means of a common scalpel; and having thus cleared away all the soft parts, the morbidly enlarged bone formed a conspicuous object. At about a quarter of an inch on the right side of the symphysis, Mr. S. commenced to saw through the jaw-bone with a small straight saw, and after making a groove in it, the short bone forceps were applied, but ineffectually. On exchanging them, however, for others with longer handles, the bone was at once cut through. A similar process was adopted at the angle, with the same success, and the detached portion of bone was then removed by separating the lingual and other muscular branches which confined it to the soft parts in its neighborhood. After securing a few bleeding vessels, and cleaning the parts adjacent to the face and the wound, the edges were approximated, and confined by means of three sutures and some strapping. The poor girl bore the operation with admirable fortitude, though it lasted more than half an hour.

After the removal of the patient, Mr. STANLEY came forward and stated that this was a case of osteo-sarcoma, originating in the cancellous structure of the maxillary bone, and by its growth destroying the two lamellæ which form the external and internal surfaces of the bone, and the tumour which he

tion. He did not consider this morbid development to be of a *malignant* nature, inasmuch as it wanted those symptoms which usually attend that class of diseases. Some practitioner, who had visited the patient in the early stages of the disorder, plunged a knife into the tumour, but *no bleeding resulted*, nor did the formation of the tumour cause any pain or constitutional derangement. Still, however, it was *desirous* in these cases to practise extirpation, in consequence of the rapid growth of this fungus, and the displacement of parts occasioned by it.

A section of the morbid parts was made, and the specimen handed round to the pupils. It presented a fibrous structure, of a radiated form, including in its interstices a matter resembling albumen. The patient is doing very well.

STRANGULATED FEMORAL HERNIA.—SPHACELUS OF THE INTESTINE.—DEATH.—Mary Bradshaw, *ætat.* 59, whose appearance rather indicated the age of fourscore years, was brought into the hospital on Sunday the 6th of September, for the relief of an incarcerated femoral hernia, which had been in a state of strangulation for a period of ten days.

Mr. LLOYD, considering all the circumstances of the case, determined to operate at once, and therefore at once resorted to the knife. On an *exposé* of the contents of the sac, the intestine was ascertained to be in a state of gangrene, and adherent to the mouth of the crural ring. Under these prejudicial circumstances, it was determined merely to divide the stricture and permit the mortified gut to remain undisturbed in the sac. The edges of the wound were therefore approximated, and the patient was removed to bed, with, however, an exceedingly unfavourable prognosis. The pulse gradually degenerated, and on the succeeding Wednesday evening, although brandy, carbonate of ammonia, strong broths, eggs, &c., were liberally supplied, the patient expired. On a post-mortem investigation the peritonæum exhibited decided evidence of inflammatory action having pervaded that tissue; the strangulated intestine was in a state of complete sphacelus, and had become adherent to the interior of the sac and the mouth of the ring.

ST. GEORGE'S HOSPITAL.

DISEASE OF THE ANTRUM.

This disease was admitted into the hospital at a late time since, under the name of "Dyspepsia." Eight years previous to its being first stated to be a disease, it had been bruised

on the left side of his face and nose. During the two last years the swelling and pain of the part had increased, and several minute portions of the bone of the antral cavity were discharged at different periods through the left nostril. The treatment of the case was very simple. An opening was made through the superior maxillary bone over the alveolar processes into the cavity of the antrum. A probe was introduced, and dead bone was felt. The day after this operation the man was in a high state of febrile delirium, which was subdued by rest and antimonials, combined with Dover's powder. During the man's stay in the house, Sir B. BRODIE (at the request of his pupils that he would render the case one of instruction) made the following clinical observations thereon:—

"Here, then, gentlemen," he remarked, "we have an instance of injury of the face; at the end of eight years afterwards, portions of dead bone are discharged from the neighbouring parts, and, I may add, that they will certainly continue to be discharged for some time to come. This case leads me to speak to you of diseases of the antrum generally, and to draw your attention to the present patient, whose circumstances are interesting to the surgeon. No clear account is given of the diseases of the antrum by surgical writers.* Such cases are rare; I have, however, seen several instances of inflammation of the superior maxillary bone. I believe that in these cases the inflammation is not dependent on local causes, but is produced and caused in the same manner as rheumatic inflammation.

"Inflammation of the lining membrane of the antrum may terminate in suppuration. The cavity of the bone may be transformed into an abscess, and pus may be discharged. I conclude that such must have been the case here. Generally, when the disease runs to this height, the cause is local, and is frequently to be found in a diseased tooth. A person has a bad tooth, a molar, a cuspatus (if the fang be large), or a bicuspid. He does not like to lose it, and he puts up with the pain and inconvenience until the pulp of the tooth becomes dead and irritates the membrane lining the alveolus, like a piece of dead bone, sooner or later. Inflammation and suppuration take place, and the matter does not escape. It may present under the gum, but sometimes it is lodged at the bottom of the alveolar socket. The bone above is absorbed, the periosteal lining of the alveolus, and the membrane lining the antrum, ulcerates; the bone becomes dead, matter collects in the cavity, and the patient suffers great torture. When the antrum is affected, there is a dull constant sense of pain over the part, with lancinating

* Some of them will stare at this.

pains shooting through the cheek. There is slight effusion under the skin of the cheek, with œdema and redness. The patient may remain in this state for a length of time. The matter is discharged from the nose or not, according as the aperture may be open or plugged up. If the former, the patient feels relief from the discharge. In these cases there is generally some dead bone, but there is no difference in the symptoms, so far as my experience goes, whether dead bone be present or not, but the former is the more tedious. You may apply leeches to the part, and put the patient on the usual antiphlogistic treatment; but this does not strike at the root of the disease. The first thing is to draw the diseased tooth, which will in some cases open to you a free communication with the antrum, when the patient experiences immediate relief. Sometimes you will find the discharge from the part very trifling, and in some cases there is none at all. If this should happen, the plate of bone between the alveolar process and the antrum is very thin, and may easily be broken down by a sharp-pointed instrument, and the two cavities laid open into one, when you may explore the antrum with a probe, and if you find dead bone there, you must wait until it has exfoliated. When you have made a free opening, keep the patient quiet, and keep a catheter or bougie in the opening, to prevent it from closing up. Through this you should inject the antrum with a syringe, very frequently. If the discharge come away through the nose, well and good. If it do not, you will know that the opening between the turbinated bones is closed, and the case may become troublesome. Suppose that the alveolar socket is filled up with dead bone. You must then make an opening. You would not make it through the jaw, because that is a bad place. Raise up the cheek, and then with a scalpel divide the membrane above the alveolar process of the molar teeth, and, having exposed the bone, make a circular opening in it, with a strong trocar-shaped instrument. The instrument must be strong, or else it will break instead of the bone. I used a pair of strong sharp-pointed scissors in this case, the other day, because I had no other instrument at hand, when I introduced my little-finger into the antrum, and was enabled easily to hook out every piece of dead bone. There is a plug in this wound, to keep it open, and it is frequently syringed out.

"Some writers describe a polypus of the antrum, and have given descriptions as to how it is to be tied and extracted. This is perfectly hypothetical. I never met with a case of the kind, and I do not believe that I ever shall.

Malignant diseases, such as fungus hæmatodes and carcinoma, affect the antrum. They grow from the inner lining membrane

of the cavity. They at first cause but little pain, and show no symptoms by which they can be recognised; but by-and-by the tumour enlarges, pressing outwards on the cheek, upwards on the orbit, and downwards on the palate bones, extending itself, in fact, in every direction. The bony substances of the antrum and alveoli become destroyed, and the teeth drop out. The tumour increases, the walls of the antrum ulcerate, and the fungous growth protrudes. The cheek now becomes affected, and the eye may be pushed out of the orbit, causing blindness, or the roof of the mouth may be broken down, and the tumour press upon the tongue and nose. The growth of the part now becomes more rapid; there is a profuse discharge, and occasional bleeding from its surface; the patient becomes weak, gradually sinks, and dies. I do not know anything more distressing than the death-bed of a patient in this disease. There is a paper on this subject by Mr. TRAVERS in the *Medico-Chirurgical Transactions*. Such cases are, unfortunately, not rare. I suppose it must have been the occurrence of these cases which led to the idea of polypus of the antrum. Some have supposed that these may be removed by being turned out, or by the application of the actual cautery to them. DESSAULT I believe it is who had a case of this kind in which the patient remained free from the disease for three months; but you know that a malignant disease may return after twelve months. I tried the method of proceeding by turning out the tumour; the cheek bulged out, and the bone had been absorbed. With a scalpel I cut down upon it; the tumour was soft, and broke down, but I turned it out. There came on most frightful hemorrhage, and I plugged the antrum with blue lint, hoping that it might slough out. It did so partially, but the patient was not cured, and he died soon afterwards."

The perambulation of the hospital is in regular periodical progress for the session. From the senior surgeon down to the deputy-assistant surgery man, and from the apothecary's sub-assistant down to RODERICK MACLEOD, all are at their posts, and there will continue—*pro tem*. At present, "one o'clock" finds them all on the move. Notice of every operation, autopsy, and inquest, is punctually posted up. Clinical lectures are given by Dr. SKYMOUR every Saturday, at four p.m.; by Dr. WILSON on pathology, every Monday at half past two p.m.; by Mr. WALKER on some surgical case, on Thursday at a quarter before 4 p.m.; Sir B. Brodie every Tuesday at one p.m. on a surgical subject. These, "clinical lectures," as they are called, are the only ones which are ever any "interesting."

● ADVICE TO HOSPITAL PUPILS.

On opening the "Clinical Course" on surgery, Sir B. BRODIE addressed the following remarks to the junior pupils:—

"I propose to commence a course of clinical lectures, and in each lecture I shall speak to you of some one case in the hospital, and in order to investigate some of the important cases fully, I may perhaps deliver you three or four lectures upon one subject. This, however, I shall not do frequently. To explain to you these cases, however, is only one object of a clinical lecture. To know surgery well, it is necessary that you should know anatomy, chemistry, and materia medica, for these only will give you a clear insight into its practice. On entering an hospital to study cases, it is not merely necessary to study them to enable you to pass an examination at the College and Hall. You should observe and study the cases for yourselves. That is the only way to extend your information. When I examine a young man at the College, I esteem the knowledge which he has acquired by inquiring for himself, much higher than that which he has acquired by lectures. The explanation of hospital cases is of great service. The clinical observations which we make to you at the bed-side of the patients, can be heard but by few; I say you should therefore notice the cases for yourselves. I advise you to go round the hospital frequently. Go round with the surgeons, the house-surgeons, and even with the dressers and senior pupils, for those gentlemen have seen more of hospital practice than you, and can therefore give you much information on many subjects with which you are as yet unacquainted. There are always to be found cases of greater or less importance in the wards; but of these the latter should more particularly attract your attention. Many will pass by cases of cut fingers, or sores, or little fractures, as trivial affairs; but will you not continually meet with such cases in private practice? Make it your business, therefore, to understand them. Your first attention in the hospital should be directed to these, after which you may proceed to those of greater importance, which are only made up of minor effects. In a compound fracture, for instance, you have two minor points, a wound and a simple fracture, making up a greater one—a compound fracture. If you do not understand either of these minor ones, how are you to understand this? If in going round the wards you are told of a swelling sore, go and look at it yourselves, and be any thing about it that you can. Ask the house-surgeon, or the more experienced surgeons, you may depend upon them so much as I found

this very much to be the case when first I began to lecture on surgery, and I soon discovered that there were a great many subjects to be treated of in my lectures, a knowledge of which I had yet to acquire. Be very minute in your observation of symptoms, as you may otherwise omit much that is valuable in the diagnosis of a case. There is only one way in which you can study cases sufficiently to remember them, and that is by taking notes of them for your own use, once or twice daily, or at certain periods, as may be necessary to impress the facts on your memory. I have been in the habit of keeping notes of many cases. When I commenced practice, I took down notes of every case. Now I take down fewer notes, and only those that are important. I have many volumes of these notes by me, and do you suppose that I find them useless? Do you think that I consider them as waste paper? By no means. On the contrary, I derive very great advantage from a reference to them. Take notes of cases then, and take them fully: there are no opportunities for study so useful as those which occur in an hospital. Years of private practice will not yield you the same advantages. Let me therefore urge upon you most strongly, not to neglect your hospital studies."

INGUINAL HERNIA, NOT STRANGULATED NOR REDUCED.—OPERATION.—DEATH.

WILLIAM HARRISON, admitted Sept. 14th, at 12 o'clock at noon. Sir Benjamin Brodie being absent, Mr. Cutler, the junior assistant surgeon, took charge of the case. On examination, there was found a punctured wound at the upper and inner part of the left thigh, on a line even with the base of the scrotum; and a large tumour of the left side, of the usual size, and occupying the usual situation, of inguinal hernia. The man stated that he had been afflicted with "the windy rupture" for fourteen years, but that up to the present time he had been always able to return it easily. Four days ago he met with a fall, when a metal spike ran into his thigh, and at the same time he received a blow from an iron rod over the part now occupied by the hernial tumour. These he stated to have caused the descent of the hernia, which has been down ever since. Mr. Cutler saw him immediately on his admission, and after examining the case, he requested the opinion of Mr. Keate (who was going round the hospital at the time) upon it. The surface of the skin covering the tumour was red; and, in the opinion of some gentlemen present, crepitated upon pressure, indicating inflammation of the cellular tissue beneath. We could not, however, detect any symptom of the kind. The lower part of the tumour was harder (Mr. Keate supposed it to contain omentum) than the upper, which was elastic, and was driven

down, upon the patient attempting to cough. A probe introduced into the wound of the thigh did not pass to any distance under the skin. There were no very urgent symptoms present; there was no vomiting or hiccup, and Mr. Cutler, we were told, was rather doubtful as to the tumour being a hernia at all. Yet it seemed very evident to every one else in what the disease consisted. Mr. Keate remarked that there were no urgent symptoms present, but that eventually the operation must be performed. The man was then we believe put into the warm-bath, and the taxis was employed, but ineffectually. He had been twice bled before his admission.

At 3 p.m. Mr. Cutler performed the operation, assisted by Mr. Hawkins. The layers of fascia were successively divided upon a silver director, until the sac was opened, and a large knuckle of healthy intestine from the sigmoid flexure of the colon protruded. Mr. Cutler pushed his finger up to the external abdominal ring, and declared that the intestine was not strictured by it, but that it was *quite free*. Mr. Hawkins pushed his fingers down to the bottom of the sac, and passed them completely around the gut; but, after further manipulation, the intestine was not reduced, but left extruded from the abdomen, and the wound was united by sutures. After the man had left the operating theatre,* Mr. Cutler made some remarks on the case to the pupils present, the precise meaning of which we were unable to comprehend. Indeed we doubt whether any of the pupils who witnessed the operation were able to understand why it was performed; nor was it until in a conversation between Mr. Cutler and Mr. Lane, when the latter gentleman made some general remarks upon the case to those around him, that any one could account for the circumstance of a hernial sac being simply opened and sewed up again. Mr. Lane said that the contents of the hernial sac consisted of a portion of the sigmoid flexure of the colon uncovered by peritoneum; that it had become attached by longstanding inflammation to the base of the sac which rested on the contents of the scrotum, and, by its posterior surface, to the anterior and inner surface of the muscles at the superior part of the thigh. These old attachments not being able to be broken down, the intestine was prevented from being returned into the cavity of the abdomen. It therefore follows that the statement of the man, previous to the operation, that he had been always able to reduce

the swelling, until the preceding four days, was untrue. Immediately after the operation he was ordered, *Calomel*, five grains; *Compound Extract of Colocynth*, ten grains, to be taken immediately.

On visiting him in the evening, six hours after the operation, he was found much easier. The tongue was moist, the pulse 80 and compressible, and he complained of no fixed pain. The bowels had not been relieved, and he was ordered *Sulphate of Magnesia*, two drachms; *Infusion of Roses*, one ounce and a half, every three hours: and Soda Water for common drink.

Sept. 15. At half past twelve Mr. CUTLER saw him; the bowels had not been opened, and he had passed a restless night; the tongue was dry, and furred in patches; the pulse 85, and full. There were also general pain and tension over the whole abdomen (which had been fomented with warm flannels), and severe headache. He had been ordered three grains of calomel every four hours. On finding the patient in this state, Mr. CUTLER appeared anxious to "draw off the wind" from the belly, as a means of relieving him from the severe tympanitic tension under which he laboured. The man was ordered to lie on his right side, whilst Mr. CUTLER introduced an elastic tube into the rectum. This came in contact with the hardened feces, but did not bring away any "wind." A catheter was then introduced, and forced through a mass of feces, and a stilette was passed through the catheter, but no evacuation followed. Two stomach-pumps (Weiss's and Read's) were now procured, and an œsophagus tube was introduced, and warm water was attempted to be injected per anum. The mechanical action of Mr. Weiss's instrument not being understood, it proved to be of no avail, and Mr. Read's was used instead; about a pint of water was injected, which the patient was unable to retain, and which served only to wet the draw-sheet on which he lay. Every method of drawing off the wind having failed, the man was left at rest, and the calomel ordered to be continued. The patient frequently complained of faintness, and vomited a little after the attempts at "drawing off" were discontinued. He was allowed beef-teen for diet. Mr. Cutler's reasons for acting as described, were founded upon his having followed a similar course in a "stone case," with great success; but doubts may fairly be entertained of the propriety of irritating the mucous membrane of the bowel near to the seat of a half-strangulated irreducible hernia which had undergone a tolerable degree of manipulation scarcely twenty-four hours before. The justice of this opinion is somewhat confirmed by the fact of the bleeding the man in the operation which was performed on himself, to the

Vespere.—The

* The man was lifted from the operating theatre to his bed in Drummond ward, but owing to some great neglect he was, before the operation, walked into the theatre. The porter and surgery-men are new in their vocation, and like machinery on the first night of a pantomime, they work very "stiff."

opened; there is less tension and pain over the abdomen since the bleeding, and pressure can be borne. The blood is highly cupped and buffed; pulse 80 and small; tongue moist; has not been sick since the morning; slight singultus; countenance anxious.

16. He was again bled last night to the amount of six ounces; the blood is highly buffed and cupped; and has been again bled by the house-surgeon to twelve ounces this morning, the blood being as much cupped, but less buffed. The pulse is 100 and small, the tongue moist, and countenance less anxious, but the bowels have not yet been opened. He passed a restless night, and is still restless; there is less tension and pain of the abdomen. His diet is beef tea. He was ordered *Calomel*, three grains; *Compound Extract of Colocynth*, ten grains; to be taken immediately. The prognosis of the case has now become unfavourable.

Temper.—He is worse than at the morning visit; the bowels have not yet been relieved. Since the morning he has taken two doses of castor oil of one ounce each. Pulse quick and full, 100; abdomen tense and painful; countenance anxious; he is very restless. Soda water for drink.

17. On visiting the hospital this morning, his bed was vacant, and his body about to be removed to the dead-house. He sunk gradually, and died about twelve at noon. Purgative medicines, colocynth and calomel, calomel and opium, and croton oil, had been administered to him, but without the least effect, and from the time of the operation until the hour of his death, the bowels were never relieved. The last medicine he took was port wine.

Autopsy twenty-four hours after death.

On opening the cavity of the abdomen, the general appearance presented by the coats of the intestines, was that of severe inflammation. On examining more particularly that portion of the sigmoid flexure of the colon which was extended through the abdominal ring, it was found to be deeply injected with blood, the red vessels appearing very prominently through the thin tunics of the bowel. It was not strangulated, and was returned very easily into the cavity of the abdomen by Mr. LANE, who was present. There was no band connecting it to the bottom of the sac, and nothing but a thin adhesion between one of the appendices epiploicae, and the posterior part of the sac (which might easily have been broken down) prevented its complete return within the external ring. These are the only pathological points in the case which were examined. The cavities of the peritoneum were not examined.

The appearances which the external ring presented appear that it had been affected by severe in-

flammation of the bowels, following a blow over a portion of extruded intestine. These symptoms were followed by constipation, hiccough, and vomiting. The operation was performed to relieve these latter, which it failed to do. The constipation was attempted to be relieved by purgatives given only by the mouth, the few injections that were administered being too mild (consisting principally of castor oil and sulphate of magnesia) to be of any service; whilst the severe inflammation was combated by four general venesections, of no great amount, the first of which was only performed twenty-eight hours after the patient had been in the hospital. Had the operation not been performed, and the venesection and purgation been pushed to a greater extent, and had a generally holder line of practice been adopted, the termination of the case would probably have been different.

Some doubts, we believe, were entertained as to the propriety of holding an inquest on the body. It was, however, eventually determined that one should be held,—when the assembled jury with an ignorant coroner at their head (on what evidence we know not), returned a verdict of “Died from Mortification.” The morbid appearances afforded no ground whatever for the verdict, and a gentleman of competent anatomical and surgical acquirements, who also carefully examined the parts implicated in the hernial protrusion, informed us that he could discover nothing approaching in its pathological appearance to either sphacelus or mortification.

LOCK HOSPITAL.

CASES OF GONORRHOEAL DISCHARGE ACCOMPANIED WITH CONDYLOMA AND CONDYLOMATOUS ULCERATION.

CASE 5.—Margaret Gawlor, ætat. 18, admitted, Nov. 17, under the care of Mr. WALKER. She has been on the town three months, and has had a discharge from the vagina nearly the whole of that time. The condylomata, with which she has been affected, have been present for two months. The vaginal discharge was preceded by a scalding in passing her urine. At the commencement of her complaint she took six calomel pills, one every other night; this affected her mouth, which is somewhat sore now. There is at present a profuse, thick, yellow discharge from the vagina, which exhibits some preternatural vascularity over the vestibulum and orifice. There is an irregular gray sloughy ulceration over a patch of confluent condylomata, elevated much above the surrounding skin, and presenting more or less a warty character and appearance, occupying the entire margin of

nal discharge for the last five days, and the scalding is almost gone. The gums are sore and tumid, but there is little pyalism. Medicines to be continued.

10. The condylomata have all gone. The gums are very tender, and at the back part of each side of the jaw they are ulcerated. She says that the vaginal discharge has returned. The pills to be continued, and the strength of the injection to be increased.

26. She is much better; the vaginal discharge is pale and small in quantity. The vestibulum is blue and vascular; pyalism continues; the gums are florid, but not so much ulcerated. The same plan of treatment was persevered in until the 7th of August, when she was discharged cured.

CASE 7.—Ellen Trevelyan, ætat. 20, admitted Nov. 20th, 1831, under the care of Mr. WALKER, with condylomatous labium, gonorrhœa, and bubo. The history which she gives of her present complaints is very imperfect. She has been married ten months, and says that soon after her marriage she had scalding pain in voiding her urine, which has gone off and returned again several times since, but she has remarked no discharge until six weeks since. She has had a bubo and condylomatous affection for one month. She has had no connexion for three months, and has only taken a little opening medicine. She has at present a very abundant thick yellow discharge from the vagina, with much scalding pain in passing her urine. There is enlargement and thickening of the left labium with superficial condylomatous ulceration along its inner margin, and there is one insulated condyloma at the inferior extremity of the right labium. The bubo is in the left groin, of the size of a walnut, and not at all painful; the inner surface of the throat is slightly vascular; the tonsils are enlarged, more particularly the right, general health good; tongue furred; bowels confined; catamenia regular. She has never been pregnant.

22. She was ordered to take the *White Martine* tinct twice daily, and to use the *Saturine Lotion*.

28. The vaginal discharge is nearly gone, and the scalding is much diminished. The labial inflammation remains the same. A few spots of lepra have appeared on various parts of the body within the last few days. To take *three grains of Calomel and three grains of Rhubarb* at bed-time, and to use the bath twice a week; a Blister to be applied over the bubo.

She says that the discharge from the vagina has stopped, but that some little remains. She complains of great pain in the throat, but does not advert to any soreness. The bubo is very small, and the eruption on the

skin is of the *tubercular* character, and does not partake of the characteristic appearance of *lepra*, there being a circular deposition on the cutis, though under a slightly desquamating surface. Those spots which first appeared on the skin, are now so far advanced as to have left only a brown syphilitic stain on the skin. Some of the characteristic symptoms of the case bear now an apparent resemblance to a secondary eruption, succeeding to condylomata; although the ulceration at the inferior margin of the right labium does not partake of all the characters of condylomata. To continue her medicines.

Dec. 2. She is much better to-day, the tubercular eruption is thicker on the skin, partaking of a mixed character of *lepra* and tubercle, some patches having the distinctive characters of each, whilst others assume the appearance of an intermediate variety which has been named small psoriasis. There is one leprous scab with some surrounding redness under the right scapula. The case exhibits specimens of the three varieties of eruption, of simple stain on the skin, *lepra*, *psoriasis*, &c. On closely questioning her, we learnt that about three weeks since, she remembers having a sore on the lower extremity, which bled.

6. The eruption is increasing, there are light yellow scabs over the scalp around the roots of the hairs. There are several well-marked spots of *lepra* on the skin, but fewer of *psoriasis*. Some of the glands of the neck are swelled; she is very weak and low, with some disposition to syncope. Many of the symptoms being now severely aggravated, and the decided syphilitic character of the disease not to be doubted, Mr. WALKER determined to put her on a mercurial course. She was ordered to apply the *Black Wash* to the ulcers, and to rub in half a drachm of the *Mercurial Ointment* every night.

13. She is very much improved in health; the syncope and trembling subsided soon after she commenced taking the mercury; there is now incipient pyalism, with a copious taste in the mouth. The cuticular eruption has much subsided, and some of it is desquamating. The excoriation and ulceration of the labium have healed, and the thickened appearance of the parts has gone down. *Blue Pill* five grains; *Extract of Henbane* two grains: to be taken in a pill twice daily.

20. Her improvement has been very rapid. The eruption over many parts of the body has quite gone, and in others there is only a scabby stain left; there is but little thickening of the labia left; she complains of some pain over the epigastric region soon after taking the pills; there is free salivation present; there is slight puffiness over the left cheek, and the gums behind are found to be slightly ulcerated. She was ordered

Blue Pill four grains, *Extract of Hemlock* three grains, in a pill twice daily. The *Black Wash* to be continued, and the *Alum Gargle* to be used to the month.

Jan. 5. The eruption is very nearly gone, and there is but very little remaining thickening of the left labium; the right labium has more of its natural feel and appearance; the discharge from the vagina is only small in quantity and temporary in its appearance; the tonsils are much diminished in size; the pyalism still continues. A lotion of *Oxymercure of Mercury* gr. j, to ℥j of water, to be used, and the injection to be persevered in. She continued the use of these remedies for some time, and was made an out-patient for a few weeks, when she discontinued her attendance at the hospital, being quite cured.

five. The operation was somewhat delayed in consequence of the unusual smallness of the nerves surrounding the artery; but, ultimately, not the least branch of nerve was included in the ligature. An amputation above the knee, for strumous disease of that joint, was afterwards performed by Mr. B. Cooper. On the 7th, lithotomy was performed upon a man aged about forty-five or fifty years, by Mr. Key; the patient is likely to do well. The convenience and advantage of the students at this hospital would be much served, if surgeons were to attend on operation days with more exactness as regards time, than they sometimes observe; much thumping of boards and panels, and other sources of unsuitable noise, would then be spared, which is painful to the patient and derogatory to a scientific audience.

LONDON HOSPITAL.—On the 3rd instant the operation of lithotomy was performed at this hospital upon a boy about ten years of age, by Mr. Luke. Some difficulty was experienced in the extraction of the stone, owing to its magnitude, as it measured in the longitudinal direction an inch and a half; transversely about an inch. The calculus was of the cystic oxide kind. The patient did well.

GUY'S HOSPITAL.—On the 5th instant the operation for tying the femoral artery was performed at this institution by Mr. Key, upon a man of about the age of thirty-

CORRESPONDENTS.

Many reports of Societies, papers, and answers to Correspondents, are unavoidably omitted this week from want of space.

ERRATUM.—In the account of the Parisian hospitals, page 129, the paragraph under the head of "HOPITAL DE LA CHARITE," beginning with the words, "This hospital is the next largest in Paris," should have been placed, in arranging the matter for publication, under the table immediately below, which is headed, "HOPITAL ST. LOUIS." Will our readers be so kind as to mark this transposition with their pens.

CLINICAL LECTURE

ON

DELIRIUM TREMENS,

DELIVERED BY

DR. ROOTS,

On Monday, October 26, 1835.

I HAVE selected a case, gentlemen, for my first discourse with you, which I consider to be one of very considerable importance in a practical point of view; and although, perhaps, some of you did not see the patient, yet I observe many present who watched the case very attentively throughout its progress. It was a case of affection of the brain and nervous system. I shall read to you the report of the clinical clerk, detailing as I proceed the principles on which I was induced to treat it, and afterwards speaking of the disease generally.

Henry Grey, a man above the ordinary stature and rather of a robust habit, aged 39, was admitted on the 9th of August, with a statement by his mother that for the last twenty years he has been subject to fits. In those fits he usually falls down suddenly, becomes perfectly insensible, and experiences convulsive movements of the limbs, and in that state he remains for a few minutes, or perhaps even for a quarter of an hour. She states that he neither bites his tongue, nor froths at the mouth, but discharges large quantities of flatus from the stomach when the fit is over. It is added, that occasionally, instead of falling down, he walks some distance in a perfectly insensible state; and since the occurrence of a very bad fit which happened twenty years ago, he has dragged his right leg after him, at the same time suffering of weakness in both legs. He died a half ago, after having received no medication for three successive days, similar to the case of the patient, but stated it

then to have been more severe. It appears that he has been lately in very difficult circumstances, from poverty, which had acted much on his mind, though on Thursday the 6th of August, three days before admission to the hospital, he contrived to drink a bottle of wine. On the next day he did not appear to his friends to be perfectly rational. On Saturday he fell down in a fit, and from that time he has had delirium. The irrationality increased from the time he had the fit. He was admitted on a Sunday, (I did not see him then,) and his skin was hot, and his forehead pale, and perspiration stood upon it; he was continually delirious, talking incoherently, and repeatedly uttering the same words again and again. His face is stated to have been flushed, and the pupils to have been contracted, contracting still further on the application of light. His eye was so bright, his countenance not his natural aspect. His speech was accompanied by laughter, as his own jokes. He says that he feels no pain any where but in his feet. The head is free from pain. Now the reason of his complaining of his feet you will see in a moment. The medical man who had visited him before he came into the hospital, had very properly directed his feet to be put into warm water; and into warm water they had indeed been inserted, for they had actually been boiled, and now presented complete masses of blisters. Every one of his toes had some portion of the cuticle separated from it, and he seemed fully aware of their condition. His tongue he puts out after a little solicitation; it is very slightly coated, and rather dry; there is no tenderness of the abdomen, but it is rather tumid at the lower portion, and he discharges a good deal of flatus per anum. His bowels were operated on by medicine before his admission, and he was bled twice, and had leeches applied to his head. His pulse on admission was 120, full, and admitting pressure.

Well now, when Mr. STONE saw him in this condition on his admission into the hospital, considering, and very properly considering, the state of his pulse, he ordered sixteen ounces of blood to be taken from the arm, directed a cold lotion to be applied to

the head, and had three grains of calomel given to him every six hours. The report next day states that he passed a very restless night, that he was delirious and raving at intervals; his head and skin were very hot, but yet they were copiously bedewed with perspiration. He complains of nothing but his feet, and asks every body who goes near him to loosen the straps. You ought to be informed that he was brought to the hospital in a strait-jacket, and remained in one ever since, and had been fastened to the bed by leather belts. The tongue is now pretty clean; the pulse 120, and rather jerking. He continues in much the same state, raving, and talking indecently and lewdly all the day. Now it was at this time that, happening to be at the hospital, though it was not my day, I was requested to see him. I do not know that it would have been absolutely necessary, even if there had been proper people to sit by his bedside, to have confined him as he was confined: indeed, it is quite impossible here to have people employed for that purpose in the case of every such patient, for a dozen similar patients may be in the hospital at the same moment; it therefore became necessary to confine him in another manner,—in the manner I have stated. Well, on carefully examining the case, and finding there was heat of the head,—finding that the pulse bore a considerable degree of pressure, and that the tongue, though not much coated, was still a little drier than one would have expected in the disease—in the true disease, (of which I shall speak by-and-by,)—finding these things, and taking the history of the case into account,—its occurrence after intoxication or excessive drinking,—excessive, when compared with the abstinence which he had previously been obliged to undergo,—taking also into consideration the nature of his delirium, which, although he talked, and hallooed, and raved, was, notwithstanding, not difficult to subdue; and finding, in addition, some tremor in the hand, and some tremulousness in the tongue, I pronounced the case to be, and now present it to your notice as, a case of *delirium tremens*,—that description of delirium tremens which has been considered by some authors as the second species of delirium tremens, namely, delirium tremens with high vascular action in the membranes of the brain, or in a portion of the brain itself, or in both; or, in other words, irritation of the brain,—with inflammatory or congestive action going on in that organ.

Perfectly agreeing, therefore, with the propriety of Mr. Stone's treatment as regarded bleeding the patient, but knowing that *further* bleeding should be had recourse to only most cautiously, I did not hesitate, under those circumstances, to repeat the bleeding *moderately* and *locally*, by ordering eight ounces to be taken with the cupping-

glasses from the occiput, and directing half a grain of the *Mur. of Morphia* to be given him in conjunction with the calomel, which had previously been prescribed every four hours, directing that the calomel should be given every four hours instead of six.

Now the *prognosis* in this case was exceedingly doubtful. You are to remember that the man had for twenty years previously been the subject of epileptic attack; that he had also been the subject of a previous attack of a similar kind, and therefore it was not unlikely that he might be suffering under some slow change of structure in the brain itself, or its membranes, consequently the prognosis was exceedingly doubtful. Still I was satisfied that the correct mode of treating the case was to diminish irritation by means of large doses of morphia or opium, and at the same time to relieve congestion or inflammatory action by moderate depletion.

The report of the next day, August 11, states that during the first few hours of the night he had only a few seconds of sleep, and that he then awoke, and raved most furiously; but that towards morning he had three hours and a half of sleep, and that when he awoke he appeared to be better. He is now much quieter; he is more rational, and appears to know some of the events of the preceding day; he still wanders a little, but the furious delirium is quite gone. He became tranquil after taking the two first doses of morphia. His skin is still hot, his face not so much flushed, and the pupils are rather contracted. He says that he has a little pain in the head. The pulse is 116, full, and soft. Tongue now clean and moist; bowels open. He was directed to be again cupped on the occiput, to the extent of eight ounces.

The report of the next day, the 12th, states that he passed a pretty good night, slept very well, but wandered at intervals. He is now sensible, and answers quite correctly, but occasionally talks incoherently. His skin is quite cool, and the countenance not flushed; the pupils are still contracted. He says he has no pain in the head, but he feels drowsy and languid. His hands are tremulous, and he is a little more exhausted. Tongue clean, bowels open, and now the pulse has come down to eighty, and is somewhat full. He was directed to be released from confinement, and to take the calomel and muriate of morphia every six instead of every four hours.

The report of the 13th states that he did not pass quite so good a night. There was more heat of skin, and more general excitement. He wandered a little at times, but was very quiet. The tongue was flushed; the pupils contracted. The head; more sore. The tongue clean. The pulse 88 and

He was directed to omit the calomel, and to have large poultices applied to his feet and legs.

The report of the next day states that he passed a very good night, but continued much in the same state. Pulse 82, not so full, but somewhat jerking; still there appeared to be a little more tremour, and therefore I ordered him to have a pint of coffee-tea a day. Wishing to diminish the quantity of the muriate of morphia, I directed half a grain to be given him every eight hours. He passed a very bad night after the quantity of morphia had been reduced, and was very restless, tossing about in bed, talking loudly and incoherently, swearing violently, and moving about to such an extent as to compel them again to put him into confinement. His skin became hot, his face was slightly flushed, and the pupils were contracted. Mr. STONE was called in the morning to him, and very properly gave him a grain of the muriate of morphia. After he had taken this he had some sleep, and it is stated that upon awaking he appeared to be pretty quiet. Tongue moist and clean; bowels opened four times during the night, and once this morning; pulse 94, and rather full. He was again directed to take the half of a grain of the muriate of morphia every four hours.

On the 16th the report states that he had passed a good night, and proceeds thus:—Wanders a little occasionally; face not flushed, but pupils still remain contracted; tongue moist and clean; still tremulous; bowels considerably relaxed; pulse 90; feet very sore, but not so painful as they have been. The mercury was now running off by the bowels; it had produced irritation of the mucous membrane, and it was found necessary to give him an ounce and a half of the compound chalk mixture after each stool, and to continue the morphia.

The report of the 17th states, that he passed a tolerable night, remaining very quiet, and much the same as yesterday. Pulse 94, becoming rather more feeble. It was then considered necessary, in addition to the muriate of morphia, to allow him, in small quantities at a time, a pint of porter in the course of the day.

The report of the 18th says, he did not sleep much during the night, but was quite collected. He wandered a little this morning. Countenance very natural, pupils still rather contracted. He complains of his feet being very sore. Tongue clean; bowels rather quieter than they were; pulse 94, and still rather feeble. He was directed to have a linseed-meal poultice applied to his feet, with the *Liq. Plumb. Acet.*

He was becoming rather quieter, and was directed to take a grain of the muriate of morphia every four hours. He was again directed to take, at about

seven o'clock, he was seized with a fit of an epileptic character, which continued for a long time, during which his features became distorted. I presume that the pulse at that time could not have been very much excited, for either Mr. WHITFIELD or Mr. STONE found it right to give a drachm of the *Spiritus Aetheris Sulphurici Compositus*, and a drachm of the *Aromatic Spirit of Ammonia*, in a camphor mixture, which he took; after which, it is stated, he slept soundly, having no return of the fit, and remaining much in the same state as before the fit occurred.

Then the report of the 20th of August states that he passed a very good night, and continued tranquil and rational both yesterday and on this day. The skin quite cool; no pain in his head; pupils contracted; tongue clean, rather dry; his pulse 84, and feeble. Feet not better; there is a large sore on the heel, which is sloughing. Bowels much quieter; the dose of sulphate of quinine was directed to be increased from one to two grains; and as he did not like the beer, it was directed to be omitted, and he was allowed four ounces of wine daily instead.

The report of the 21st states that he passed a pretty good night, but that during it his bowels were opened four times, and twice this morning. He is quite sensible; pulse 86, and somewhat full; his tongue a little dry in consequence of the irritation in his bowels, and it was found necessary to change the chalk mixture for some of the compound infusion of catechu.

He was directed to have a slice of meat on this day.

The next report states that he passed a good night; pupils contracted; bowels quiet; tongue moist. As the bowels became quiet, the tongue became moist; bowels open only once; pulse 90. He was directed to continue the sulphate of quinine every four hours, but to take half a grain of the muriate of morphia every six hours.

The report of the 23rd is to the effect that he continues much the same.

The report of the 24th states that he remains quite rational, but that the bowels are rather relaxed; tongue clean. It was now found necessary to add a drachm of the tincture of kino to each dose of the infusion he had been taking.

On the 25th the report states, that the bowels were more relaxed to-day. The medicine does not check the purging. He complains of some pain in the abdomen. There was a degree of tenderness there, which was distinctly traceable along the course of the colon. The stools contained a good deal of mucus, but still a considerable secretion of bile. His tongue was clean at the edges, but white and dry in the middle. Complaints of thirst. It was quite clear now that there was something more than simple

irritation going on in the bowels, which I thought it probable that the quinine helped to continue. I therefore directed that medicine to be omitted, and eighteen leeches to be applied along the track of the colon, to be followed by the application of a blister in the evening, still at the same time continuing the astringent medicines; and if the purging was not relieved by those remedies, I directed that he should have a glyster of starch, with twenty-five minims of the tincture of opium, thrown into the rectum every morning.

The report of next day states that he felt relieved, and that he had now no pain, except from the soreness of the blister. The bowels had only been opened once since the last remedies were resorted to. His tongue a little dry in the middle, his thirst less, and he remains perfectly rational.

The report of the 27th says, that his bowels had not yet been opened on that day; he sleeps very well; tongue moist, but a little coated; his face a little flushed; the skin rather hot and dry; feels thirsty; pulse 96. He was directed to take half an ounce of castor oil. For some time the muriate of morphia, in consequence of his remaining so perfectly rational, had been gradually omitted, so that by this time he had ceased to take it. It appears by the report, that the castor oil operated violently; seven stools followed its exhibition. The astringent mixture was again ordered, and it checked the purging. His bowels are a little relaxed to-day, and he complains of some tenesmus on going to stool. Tongue moist; skin rather hot; not so thirsty, and the flush has left the cheek; pulse 84. As he objected to his wine, saying that he did not like the taste of it, an ounce of brandy was given to him every twenty-four hours in gruel or arrow-root.

The report of the 29th states that he feels better. The bowels had been opened once; he has little pain except from the blister; his countenance is clearer, and natural; pupil natural; tongue a little coated; pulse 72, not very feeble.

The report of the 31st states that he has gone on very well since the last report. His bowels had not been opened for two days; tongue a little foul at the root. He was directed to take two drachms of castor oil immediately; the dose to be repeated if necessary. The first dose did not operate, but the dose in the morning produced three stools; he complains of nothing but his heels. Tongue clean and moist; pulse 74, and pretty good. The sores upon his heels are healthy and granulating.

Well, now, it was not necessary to do any thing more for this man. He went on gradually improving from the 1st of September until the 1st of October. I quitted London myself at this time, and I find that all that was further necessary to be done for

him was to order that he should have twelve minims of dilute sulphuric acid, with a drachm of gum mucilage of acacia, out of infusion of cascarrilla, three times a day, in consequence of considerable perspiration. This plan was directed on the 15th of September, and was continued, with merely an occasional exhibition of a slight aperient. He lost all tremour, he had no pain in his head, he was perfectly rational, and he was out of the hospital quite well on the 1st of October.

Now I stated to you that I considered this to be a case of *delirium tremens*, as I chose to christen it, attended with high or excited vascular action, by which I mean to imply *delirium tremens* consisting of irritation of the brain; that irritation in this particular case being accompanied by some degree of inflammatory action or congestion,—I believe of inflammatory action either of the membranes of the brain or of the brain itself. But I do not think that our time will be mispent if I just say a few words about *delirium tremens* itself; leading afterwards to that form of it under which I consider this man to have laboured.

In former days this disease of the brain and nervous system was most commonly confounded with *phrenitis*, until Dr. SUTTON of Greenwich published a valuable treatise on the subject, and pointed out how essentially it differed from inflammation of the brain, and showed that it was, in fact, a distinct and peculiar affection of the brain and nervous system,—distinct from inflammation, and therefore requiring peculiar and distinct treatment. Other medical men have since written on the subject. The term, perhaps, is one which we cannot regard as exactly correct, inasmuch as *delirium tremens* is a term which certainly implies a something that does not take place. The *delirium* itself cannot tremble. Other persons have variously christened it. Drs. PEARSON and ARMSTRONG called it "brain fever." Dr. BLAKE called it the "brain fever of drunkards." Dr. COPLAND has called it much more properly "*delirium cum tremore*." There is *delirium*, and there is trembling; therefore the latter perhaps is the better term. Still, if we distinctly understand by the term "*delirium tremens*" of what the disease really is, there is no objection to that designation.

The disease is divided into three species.

be said to be *delirium with tremour*, most probably, as Dr. GREGORY has stated, arising from exhaustion of the nervous power, and consisting wholly in irritation of the brain and nervous system, constituting the true "*delirium tremens*" of Dr. SUTTON. The second species of *delirium tremens* is accompanied with more or less tremour, but at the same time it is attended by a highly excited state of vascular action in the membranes of the brain, or in the substance of the brain, or in both; in other words, irritation of the brain and nervous system, accompanied by more or less inflammation or congestion.

Now the symptoms of the first species of the true *delirium tremens* generally manifest themselves in this way:—A patient for a time is a little different in manner and appearance to what is generally observed in him. His friends notice a little peevishness, a little fretfulness, and, at the same time, a little abstraction in his manner. He finds fault with his associates. From being a good-tempered or a good-natured man, he becomes a hasty one, and complains unnecessarily. He does not appear to be well, but at the same time, if asked whether any thing is the matter with him, he will perhaps snappishly answer, "No, I am quite well." This goes on, probably, for two or three days, perhaps for a week, in some instances for a fortnight, a change only manifesting itself in this way. His appetite fails at the same time; his nights are restless; he tosses about in his bed, and when he gets up in the morning, having had little sleep, in some instances scarcely any, he does not feel refreshed. As the disease advances, his fretfulness yields, perhaps, to some particular delusion, (or, to use what is probably a better term,) to some illusion. That illusion most commonly relates to his own affairs, or perhaps to the affairs of some particular friend; the illusion being always of a desponding character. He imagines, though perhaps rolling in riches,—or at all events, possessing every comfort, his business going on well as usual,—he fancies that every thing is running to sixes and sevens, and that he is going to the dogs as fast as he can, and that it will be as much as he can do to avoid getting into jail; or he thinks there is some conspiracy against him, or against his life,—some attempt to assassinate him. All his illusions are of a desponding, or even of a horrible character. At times—with less illusion, perhaps, as regards himself—he is busied in setting to rights the affairs of his friends. If spoken of at this time, he will answer with perfect calmness. He will tell with perfect confidence that he is in health, but directly afterwards he is abstracted, and recedes into a state of illusion, and you cannot see him. His nights are restless, and he has no sleep. He

gets out of bed, perhaps, and walks about the room during the whole night. Perhaps, before this, you begin to find that his hand trembles very much, that his tongue is exceedingly tremulous also; and now if you examine his skin, you discover that it is bedewed with a cold, clammy, sticky perspiration; and it is stated, though I cannot say myself that I have ever observed the fact, that the perspiration is sometimes of an offensive odour. During the whole of this time, however, you will find that he does not complain of much pain in his head. Often, very often, these patients do not complain of any pain in the head. Now, it is right to put you upon your guard that there will be sometimes pain of the head, and most commonly there will be a profuse cold, clammy, sticky perspiration, over the whole surface of the body, the extremities feeling cold too; there may be no heat of the head, but the head will be bathed with perspiration, though sometimes that perspiration—I will not say is wholly absent, but is so slight as easily to avoid detection, unless you assiduously look for it as one of the symptoms to confirm you in your diagnosis. Now, I stated that the tongue is, commonly, tremulous, in addition to which, if there be simple irritation of the brain and nervous system, unconnected with anything like inflammation, you will not find it dry, you will not find it rough; you will find it a little coated, it is true, but it will be coated with a white creamy moist mucus.

Now, in acute inflammation of the brain, you have not in the early stage a tremulous tongue, but a dry rough tongue; and as the disease advances, in the latter stage you have a tremulous tongue; but it is not tremulous from the beginning. The face, which affords other indications in true *delirium tremens*, is pale; the eyes are rarely suffused, but they are somewhat dull. I say *rarely*, because I have in one or two instances seen the eyes slightly suffused, but not evincing a tinge of that suffusion which you will find in active inflammation of the brain. At the same time there is no intolerance of light or noise. The pulse, if the disease comes on slowly and gradually, is, at first, perhaps, soft and slow; as the disease advances, it becomes quick, soft, and feeble; and as it still further advances, the pulse becomes rapid, and if the disease is about to terminate fatally, either unaided or not yielding to aid, then perhaps it becomes fluttering, and that sort of pulse is felt, which I do not know how to describe better, than by calling it a "fluid pulse," which seems like the flow of a continuous stream of water under the finger.

I stated to you that there was generally considerable tremour of the hands, and at the same time tremour of the whole body. This, however, varies in intensity, from being so

dition of the brain and nervous system under that state of irritation.

I have something more to say upon this subject. I have to speak of the treatment, and a little to say upon the diagnosis and the distinct points of treatment of the two species, and therefore I will postpone these divisions of the topic, as the hour has elapsed, until next Monday.

ON THE TREATMENT OF FRACTURES

WITHOUT THE AID OF SPLINTS.

By W. C. RADLEY, Esq., M.R.C.S. L.,
Newton Abbot, Devonshire.

THE illustrious Sydenham, in his old age, said, "Don Quixote is a good book: I read him still." I think and act with Sydenham in this respect, and am induced to select from the pages of Cervantes the following quotation as a preface to the observations I am about to make on an important branch of surgical art:—"At all times, in all places, and by all the learned, simple means of cure are more esteemed than those that are compound." I have watched the simplicity of nature in all things natural, and endeavour to imitate her in all things artificial,—especially in the practice of surgery; and thus it is that in the treatment of the accidents of which I am about to speak, I have been enabled to throw off the useless lumber of art in the shape of splints, and to effect cures with less pain to the patient, in shorter periods, and in a far more creditable style of surgery, than is generally possible under those old encumbrances.

Nearly twenty years have elapsed since my first attempt was made to cure a fracture without force and coercion, and success has invariably followed every subsequent effort; and I now assert, that every species of fracture which is curable with splints, may be much better cured without them. Moreover, I affirm, that splints are not only useless, but positively injurious; productive of great pain and inconvenience to the patient, and in no case can give aid to the cure. On the contrary, I consider that they retard that desirable termination of our services. Fully aware am I, that assertions which condemn the practice and views of ages, should be advanced with caution; and influenced by the considerations which innovations always create, I have hitherto been deterred from presenting my thoughts and practice in writing on these matters to the attention of the profession. As to public opinion (founded on ignorance of the

resources of nature in curing fractures and other injuries), among those persons who have been my patients, as well as a host of friends whose feelings of interest have been awakened on the subject, I used continually to find them to be active opposers of a mild system of cure. By far the greater number of persons think that a broken bone cannot be "set" without the use of force; nor afterwards retained in a proper position but by strong compression, or what I have termed coercion. In all such cases I had ever found my patients more disposed, through fear of the results, to suffer the irksome tyranny of the splint, than to have themselves allowed the use of a soft pillow.

But not so now. Opposition to the plan has ceased among them; and where my assistance is required, bystanders, though yet half incredulous, let me proceed without remonstrance, while I assure them my aim is to make the patient easy and so to keep him, referring to numerous cases in proof of its efficacy. I mention this popular prejudice in favour of long-established usage, because many preposterous modes of cure in medicine and surgery will readily occur to the mind of every practitioner, wherein absurdities no longer have a place in practice; and of which the wonder is that they should have ever been adopted at all. Let any candid surgeon read a modern catalogue of surgical instruments, and reflect on the announcement it makes. He will there find offered to him a choice of "Mr. Amesbury's apparatus" excellent of its kind, "with splints complete." There are splints bearing the names of the venerated Pott, of Cline, of Sharpe, and of Martin, "whale-bone splints," "improved fracture cradles, used at Guy's and St. Thomas's," "japanned" and even "iron splints," and, last but not least, "long splints, to reach from the foot to the arm-pit,"—to keep one set of muscles in protracted and painful extension, while their antagonists wait in an agony for their turn to move. Are these the resources of surgery in the year 1835? They constitute the abuse of surgical mechanism, which ought for ever to have given place to chemical science? When a fracture is properly reduced, the cure proceeds to its accomplishment, not on mechanical, but vital principles, assisted by rest and a genial atmosphere. I assert therefore, that mechanical aids should ever be passive and not active, where there is no displacement for the hand to reduce. All force or external pressure that produces pain is mischievous, and should be avoided.

In such a state of things, one indication alone should influence our minds,—the relief of which the patient feels. Pain, with irritation, and, in some cases, undue accumulation of blood in the limb, which is the result of the bandage; for the bandage, for the most part, does

neither the splints nor the bandage can be of use. Even if the limb be not in a malposition, yet irritation, passing into active inflammation, tends to delay the result of our efforts; and to secure ease to the patient, we should sedulously obviate those errors, and prevent the evil of malposition, by frequent examinations of the limb.

The suffering produced by fracture and its usual complications are threefold. First, the mental anguish; secondly, the pain produced by awkward motion, clumsy handling, and the supererogatory offices of "setting" by compression and restraint, and thirdly, the permanent evil consequences that too frequently follow,—evils which are much more commonly produced by maltreatment than by the simple effects of the accident alone.

Not long since, a young peasant in a neighbouring village fractured the femur rather below the centre of the shaft. Twelve weeks afterwards I accidentally saw him, with his thigh tightly splinted up, and unable to set his foot on the ground; for the muscles, by the compression, had lost the power of motion,* in consequence of which the muscular energy of the limb continued for a long period impaired, requiring much patience and assiduous discipline to restore it to health, though the patient was a hearty and vigorous youth.

Another fine athletic fellow whom I saw, by falling across a low grassy bank, fractured his femur very near the centre. Six months afterwards I saw him, weak, pale, and emaciated, with a pair of long splints bound upon his thigh with a degree of force that brought to my mind the sailor's mode of fishing a broken mast, and all this infliction for the vain and ideal purpose of keeping the bone "right," though without any such force, the limb would have reobtained its use in one fourth of the time which was occupied in the cure. Each of these was a case of simple fracture.

Let me seriously ask, Do surgeons ever apply splints to a broken rib? The practice is not possible; but does not the bone unite and heal without it, and simply with a little plaster spread on lamb-skin, although the bone is not deeply seated in and clothed with muscle like the thigh, the leg, or the arm, but merely covered by integuments; and, moreover, is repeatedly in motion, from the convulsive shock of the cough which the accident excites. There are exceptions to the rule, but they do not affect the argument.

In fractures of the clavicle, I have never heard that the inventive power of surgery has designed a splint. Yet look to the use of this osseous appendage to

the breast and shoulders, close to air, and nearly uncovered; yet not unfrequently even without surgical aid it unites, and a cure is perfected.

In fractures of the lower jaw the same method is pursued. Like the clavicle, it is merely bound round with the common integument; I think no surgeon (unless some Quixotic professor) would splint up a broken jaw. A man had the right lower maxillary bone fractured; the broken side was firmly supported in *situ naturale*, by a pad of lint and a silk handkerchief, so managed as to press most on the dependent portion. The blow was a heavy one; but after he had lain ten days in bed, he got up, moved about, could eat sufficient, talk enough, and slept soundly, until the sixteenth day from the accident, when the frolics of a country revel tempted him from home, when he got half drunk, and entered with much volubility into the particulars of his accident, the result of which was, a stiffness of the parts on the following day; but common care soon enabled him again to put the jaw to all its appropriate uses.

Long fissures and fractures of the bones of the cranium become filled up with ossific matter, and unite, with common warmth and quiet, without splinting.

If in these comparatively unfavourable situations the union of bones is perfected without the aid of splints, how much more certainly and rapidly will union take place, where the bones are imbedded in thick muscular parts possessing strong vascular action! I write at a disadvantage, because splinting has long been the custom, and the custom it will continue to be, until a fair trial shall have been given to some such plan as I am about to advocate, in which simple precepts and a greater reliance on the resources of nature, tend to make the application of the splint a barbarous and obsolete fashion.* I have waded through some quartos for the purpose of culling facts from the practice of others, to support my views in the cure of fracture, but with little success, and that of the negative kind, the statements being made without the design of militating against the general doctrine. Sir Astley Cooper's elaborate work on dislocations and fractures of the joints, is authority enough on the general employment of the "splint and fracture box" at the great London hospitals; and Dr. Bush, of Totness, a gentleman of great professional talents, on lately returning from the

* A favourite dog belonging to one of Sir Walter Carew's packs of fox-hounds ventured too near the heels of a vicious horse, which kicked back and broke the dog's leg. He was cured without splinting, for after the lapse of three days he industriously gnawed off every thing that was put upon the limb. He was continued until well, getting fat the while; and he has since hunted as before the fracture. An African pigeon, which had its thigh broken, was cured without a splint or deformity.

of compound fracture of the elbow-joint (the subject was a gentleman aged 74, a neighbour of Sir Astley's), a pasteboard splint and an evaporating lotion were used. This dressing was not disturbed until the twenty-fifth day after the accident." "The wound was some time in healing, *being prevented by the pressure of the splint.*" This suffering was endured for a month, wanting three days only, by an old man with all the fidgety uneasiness of seventy-four years upon him. I fear this case did not end to the patient's comfort at those gastronomic seasons, when he wanted to carry a cup or a fork to his mouth. This recluse system of casing up limbs from the eye for a month, much as I admire Sir Astley Cooper as an operative surgeon, takes I think from his credit for penetration into the remedial processes of the body.*

At page 259 of the treatise, we are recommended to apply a many-tailed bandage; and at page 370 "a light bandage in cases of fracture, wetted with spirits of wine and water." This application to most recent cases of fracture is decidedly bad. Let spirit be diluted with water ever so much, still the compound will be a stimulant. The first indication of surgery in these cases is to prevent heat which stimulation excites, and the second is to allay and subdue heat when it has been excited. The injury of the fracture itself, when effected with as little violence as may be, the jaggings extremities of the bone acting on the soft parts, will always be a powerful exciting cause of heat,

* A very ugly "cure" of fracture at the upper portion of the tibia, four or five inches from the inferior point of the patella, occurred to a respectable farmer in the prime of life, a few miles from hence, by a cart-wheel passing over it. The surgeon splinted and bandaged as usual. The leg was seldom examined, the real position of the fractured ends of the bones was for the greater part of the time concealed; and when the limb was examined, the soreness was so great from the pressure, and the tumefaction so long remained, that little good was done by gentle extensions from time to time, or any other kind of motion. Twelve months afterwards the good man showed me the limb. I concealed my surprise, for the projection of the superior edge of the fractured portion of the tibia, over the inferior portion of the bone, was full three quarters of an inch. Of course that projection was anteriorly and superiorly. Here was a "cure!" Why it was five years before the man could bear to step firmly with the leg, the weight of his body overhanging the line of bearing on the foot! He was told by his surgeon that all this displacement and weakness was a part of the consequences naturally attendant on so bad a species of fracture. Of course I did not disturb this opinion. I only recommended him to make "the best of a bad matter," encouraging him with the hope that time would mend it a little, under the long-continued auspices of a plastered, circular, dressed skin, and a bandage which he wore for a year, having them from time to time renewed.

irritation, and pain. But in cases where severe contusion has been unfortunately superadded, I have found ample employment in obviating the accession of heat and its effects in the use of a very weak lotion of water and superacetate of lead, or some decided sedative; or in tepid bathing, with exposure to the atmosphere to promote evaporation. This object cannot be attended to under the customary mode of proceeding.

(To be concluded.)

PECULIAR RELAXATIONS OF THE UTERUS.

By F. MONTGOMERY, M.D., Physician-Accoucheur to Sir Patrick Dun's Hospital.*

WHEN the uterus has expelled the product of conception at any period of its growth, active contraction should immediately commence, and its volume be speedily reduced to its original dimensions. But matters do not always proceed thus favourably, the uterus being liable to fall into a state of atony and relaxation. One condition of this accident, of whose existence I have fully satisfied myself in many instances, has not, as far as I am aware, been noticed by any writer, the peculiarity of it being, that it continues in a chronic form, occurring most frequently after early abortions, which, however, are not necessarily connected with any loss of blood during the miscarriage; but when the patient is beginning to take exercise, she is unexpectedly seized with considerable hemorrhagic and leucorrhœal discharges, inducing great debility and alarming apprehensions, with, most frequently, no pain, but a sense of internal fullness, which appears to her to interfere with her passing water; she has a dull aching feel in the small of the back, and is constantly annoyed by a sensation of relaxation in the whole contents of the pelvis. On examination the vagina is found unusually relaxed, and the os uteri gaping, with its lips tumid, thickened, and projecting, soft, and flabby; the cervix is dilated, its natural tapering form is gone, and the body of the uterus itself is felt to be enlarged and doughy when pressed by the finger, the organ appearing quite insensible. This condition may persist sometimes for months, with various degrees of constitutional disturbance, the discharges being sometimes so profuse as to endanger life, sometimes but slight, or only occasional, attracting attention more by their continuance, than by their symptoms.

* Condensed from the Dublin

ceur under these circumstances; but if the one of the uterus is not soon completely restored, abortion will almost inevitably happen. The details of a few cases will elucidate these points.

CASE 1.—In July, 1830, I was called to see a lady who had just miscarried in the second month of gestation, with profuse hemorrhage. She had miscarried twice already within the preceding six months. On her third occasion she *seemed* to recover well, and left her bed in a week. A tonic system of treatment now employed by me failed, and she did not cease to have vaginal discharges. I then examined the os uteri, and found it just in the state it had been in a month before, gaping open, soft, relaxed, and flabby. I recommended her to go to the sea-shore, leaving her husband behind. This was done; she took small quantities of quinine and gentian, with aromatic sulphuric acid, and bathed every day until November, when she returned home completely re-established in health, and immediately afterwards conceived, and on the 6th of the following August gave birth to a fine healthy child, which she nursed with success. She has had two children since.

CASE 2.—On the 30th of January, 1832, Mrs. V. aborted, without either pain or hemorrhage, on making water, in the third month. She had been some time before greatly startled by a hatching hen, and she now gravely asked me if I did not think what she had been delivered of was very like a chicken. At the end of a week she was able to go about as usual. Two months after the miscarriage she sent for me; from the time of the abortion she had never been entirely free from vaginal discharge, and pains, resembling slight after-pains, with vesical irritation and dysuria. I found the uterus almost exactly in the state I had felt it two months before. Tonics, free ablation of the lower part of the trunk with cold salt water, and opening sea-bathing as soon as the weather permitted, perfectly re-established her health in about six weeks, during which time she lived *absque marito*. She conceived again, and was delivered in February 1835.

CASE 3.—In the middle of April 1834, a sister to the patient Case 1, and mother of six or seven children, miscarried early in the third month, with very little pain or hemorrhage. At the end of a fortnight she went to church, felt greatly fatigued, was seized suddenly with a smart uterine hemorrhage, nearly fainted, and was conveyed home. Her medical attendant next day established a rigorous system of low diet, and for drink, full doses of laudanum,

and constant cloths wet with vinegar and water; in addition to which a bag of chalk, moistened with vinegar, was introduced into the vagina. In a week matters had become much worse, and when I first saw her, she was unable to move, and almost without pulse, and shivering from being constantly soured in wet, and the mind depressed to the lowest degree of despair. I found excessive relaxation of the vagina, the os uteri so open that it would have admitted the points of three fingers, its lips tumid, but soft and puffy, and the body of the organ enlarged and doughy. I immediately had the wet cloths replaced with dry and warm ones, and ordered a jar of warm water to the feet, a scruple of ergot of rye in warm wine; jelly, good broths, chicken, and claret; tonics as in the former cases, and removal by-and-by into the country. She was soon much better, but had remained in town, and conceived again in June, and again miscarried in August, when I attended her; there was little hemorrhage, but the uterus was still relaxed, which I obviated by rest in the horizontal position for several days, a generous diet, and tonics. I also prevailed on her to go to the sea-side, her husband remaining at home. By the beginning of winter she had completely recovered, returned, conceived again, and in September 1835 was safely delivered of a daughter.

These facts promise to be useful from suggesting to us, in addition to other considerations, the obvious indication of using restoratives for the general powers of the system, the local application of tonic agents, and the use of specific stimulants to brace the uterus; but the chain of morbid actions can only be effectually broken by withdrawing the individual for the time from the possibility of conception, the uterus being, as is said in agriculture, allowed to lie fallow for a season. I have had a case in which this relaxed condition of the uterus was ascertained by dissection four weeks after labour, accompanied by profuse hemorrhage.

The uterus was found considerably larger than it ought to be at such a period after delivery (one month); measuring 4½ inches in length, and more than 2½ in breadth; its cavity would have contained an egg; the os uteri and cervix were quite open, and sufficiently relaxed to allow the introduction of my fore-finger; its parietes were about three-eighths of an inch thick, with the structure as soft and flabby as that of any other muscle in the body, so that it might be rolled round the finger, and when divided by the knife the vessels were found uncontracted and pervious.

There is a question which very often meets us in practice which it may be proper to notice here; ought patients who have experienced considerable hemorrhage in labour to be allowed to nurse? In my opinion they ought, if no other reason interfere, be-

30th of December that
on the 5th of
4th, and again
delivered 30th.

cause the mammary excitement which accompanies the early part of lactation, propagates its influence to the uterine system, promoting there active contraction. Indeed, it appears to me very probable that chronic relaxation after early abortion (independently of hemorrhage) being so much more frequent than it is after delivery at advanced periods of pregnancy, is attributable to the want of the mammary excitement. But the nursing we may find it necessary to prohibit beyond half or a quarter of the usual period. Every day's experience convinces us, that one woman will suffer more exhaustion by three months' nursing, than will another by twelve; and one of the ill effects thus produced is, I have reason to believe, this very condition of the uterus. It is perfectly well known that when nursing disagrees, or has been too long continued, the prominent symptoms are precisely those which accompany a relaxed uterus induced by other debiliating causes, and from examinations made under such circumstances, I have learned that the condition of the uterus which I have been describing is very frequently induced in a greater or less degree. In July last I saw a lady, of apparently sound constitution, who had been nursing for nearly seven months, and presented many of the morbid effects of undue lactation, such as derangement of the digestive organs, pain in the back and left side, with almost constant slight red discharges, and occasional leucorrhœa. I found the vagina greatly relaxed, the uterus slightly descended, enlarged, and softened, and the os uteri sufficiently open to admit the end of my finger. Immediate weaning, attention to the digestive organs, tepid salt-water baths, tonics, and sea-bathing, soon completely restored her health. Dr. M. Hall says that "the uterus suffers," but he does not specify how. I have only to add to what he has said, that what "the uterus suffers" is relaxation, both of its tissue, by which its vessels are allowed to discharge their contents too readily; and of its connexions, by which it acquires a tendency to prolapse; and when patients who have unduly given milk, conceive within a short time, they very generally miscarry.

The remedies that will do most service are in these cases, preparations of cinchona, gentian, colomba chalybeates, mineral acids, country air, sea bathing, and cold topical ablution. Should the hemorrhage burst out profusely, the tampon with pressure, instantly, and the ergot of rye, are the means on which generally our greatest reliance ought to be placed. Occasionally an opiate, or the application of cold, may be used with advantage; but I cannot avoid observing, that the indiscriminate liberality with which both these remedies are applied in practice is greatly to be deprecated. A napkin is often soaked in cold vinegar and water, laid

on the external parts, and removed smothering with heat; this is only a pretence of doing good. The general principle on which cold should be used, is that of its sudden application, as a stimulus to contraction, and not from its refrigerating power. With regard to the ergot of rye in cases of protracted menorrhagia, the specific action of that remedy is strongly confirmative of a belief that those discharges are often dependent on the relaxed state of the uterine fibres we have been considering, constantly leading to a suspicion of organic uterine disease, a suspicion which a vaginal examination rather tends to confirm, the organ being found increased in size, with the cervix and os uteri tumid and puffy; and I am strongly disposed to believe that this is really the condition of the uterus represented by Madame Boivin, 23rd Plate, Fig. 1, which she describes as "a scirrhus tumefaction of the posterior lip of the os uteri, taken from a woman who died of pulmonary consumption, after an abortion in the sixth month."

POISONING BY HYDROCYANIC ACID.

By T. G. GEORGHEGHAN, M.D., Prof. of Med. Juris. to the Coll. of Surg. in Ireland.

THE particulars of the following instance of poisoning with hydrocyanic acid were related to me by the individual himself, and those who witnessed its effects:—

A gentleman, aged 21, being subject to uneasiness in the stomach, was induced to have recourse to hydrocyanic acid. He commenced with one minim of the acid of the Dublin Pharmacopœia (sp. gr. .998); this dose he repeated twelve times the first day, without any perceptible effect. On the following day he took half a drachm, on the third a drachm, which he repeated on the fourth day, and on the fifth day a drachm and a half; all without effect of any kind. On the sixth day he increased the dose to two drachms, and two minutes afterwards (a sensation of extreme bitterness being produced in the mouth), having walked a few paces, he experienced a feeling of great confusion, with headache, and loud ringing in his ears. With difficulty he retraced his steps, leaned forward on a table, became insensible, and then fell backwards, remaining in this state three or four minutes, during which time he was violently convulsed, and, to use the expression of the medical gentlemen present, affected like a man poisoned with the acid. After becoming insensible, and while on the table, his thighs were raised, and his abdomen, and right arm, were thrown to the ground. The face was extremely

also rigid; and on drawing them from the side, they forcibly reverted to their former position; the eyes were shut, and the muscles of the face violently convulsed. The teeth being clenched, the solid sesqui-carbonate of ammonia was applied assiduously to the nostrils, and he was shortly able to swallow a little fluid. (Two drachms of the spiritus ammoniæ aromatisatus were diluted with a little water to give to the patient.) Vomiting supervened with great relief, and in half an hour he was quite well, with the exception of pain and a feeling of distention in the head, which continued for the day. His old complaint was completely removed by this extraordinary dose. The acid taken on the various occasions was diluted with water; the total quantity consumed being a little more than six and a half drachms of an acid, the per centage of real acid in which, according to Ure's table, should be 1.5.*

The above case was witnessed throughout its whole course by persons competent to observe the symptoms, thus affording an opportunity of acquiring data which are seldom to be obtained where this agent has been taken by accident, or for self-destruction. In a paper on the treatment of this form of poisoning in the *Annales de Chimie*, vol. 43, by MM. Persoz and Nonat, the symptoms are divided into three stages: 1. General malaise (or giddiness); 2. Tetanus; 3. Interrupted respiration, or what Orfila occasionally terms the stage of flaccidity and insensibility, during which the pulse rapidly fails, and finally becomes extinct. I have frequently observed animals to which this acid had been administered, perform rapid motions with the mouth and jaws, as if a powerful impression had been produced on the nerves of taste. Coullon (Paris, 1819) states that in experiments on his own person, he experienced, from doses varying between twenty and eighty-six drops of the acid (of Vauquelin?), an insupportably bitter taste, nausea, hurried pulse, weight and pain in the head, succeeded by

a feeling of anxiety, which lasted about six hours. In man I have observed that the coma is often well marked previous to the convulsions. In animals, on the contrary, convulsions frequently, if not generally, precede coma.

In the case detailed, vomiting was not present at first. This symptom is mentioned by some writers as indicative of a fatal termination; but recorded instances afford reason for concluding, that although late in the order of symptoms, it is generally a favourable one. In the present case it was followed by great relief; and Coullon mentions many instances in which even alarming symptoms were dissipated on spontaneous vomiting. In its toxicological relations there can be no doubt of the propriety of classing it amongst the narcotic poisons, though it seldom produces sleep. Its therapeutic action, however, appears to demonstrate the propriety of placing it amongst "sedatives," as has been done by Dr. A. T. Thomson.

The property of hydrocyanic acid, of often not acting in certain doses, while a slight increase in the quantity produces violent effects, appears to have been hitherto little noticed by writers, but it is obviously of considerable importance, and leads to the consideration, whether under any circumstances it can be considered as possessing an accumulative power. Whether there be conceded or not to this poison a power of accumulation, it should be borne in mind for many reasons, that minute difference in dose is capable of producing the greatest disproportion in effects. Occasionally the acid presents the most extraordinary anomalies in its action. Thus, Richard knew a patient take even twelve ounces of laurel water, prepared by one of the first pharmacians in Paris, in the twenty-four hours, without any symptoms of poisoning. Dr. Montgomery failed in killing a cat with a drachm of the medicinal acid, while a drop and a half of the same acid (kept for three years longer) almost instantaneously destroyed a rat. In the great majority of experiments which I have made on the subject, young animals have been less sensible to its action than old ones. The interval which may elapse between the swallowing of the poison and the commencement of its action, became a question of great importance in the trial of Freeman for the murder of Judith Buswell at Leicester, April 2, 1829. Five drachms of the medicinal acid had been taken, and the bottle was found corked and wrapped in paper beside the head of the deceased, who lay in a composed position. The question arose, could the deceased, after taking that quantity, have had time to perform the various acts which her position and surrounding objects indicated? In the instance detailed first in this paper, a quantity equal to twenty-five drops of the

* From a careful examination of two distinct portions, I ascertained the per centage of real acid to be .60. Therefore the reported strength of the acid of the Dublin Pharmacopœia is 2½ times that of the acid employed in this case; and the per centage of the acid generally used in England, if correctly prepared and carefully preserved, is five times as great. From calculation, however, grounded on the quantity of materials employed, the strength of the acid of the Dublin Pharmacopœia should be about three per cent.; the acid which was used in the instance under consideration was prepared from the ferrocyanide of potassium, and it should be mentioned, that its chemical examination was not undertaken for several weeks after its employment; it had been carefully preserved, and, when I got it, was found to possess strongly the characteristic of cyanogen. It is also well known to be very strong, will retain its strength for a long time, and, in the light of day, undergoes no change more than two

English acid, of three per cent., commenced to act in about two minutes. Should twelve times as much, or five drachms, begin to operate in the one-twelfth of the time, or ten seconds? Within that period the acts of Judith Buswell could certainly be accomplished. A proportion not differing very materially from this may be found to exist. As to the smallest quantity capable of producing death in the case I have detailed, the quantity of real acid amounted to .7 of a grain, which was almost the same as that taken by the epileptics in the dreadful accident which occurred at one of the Parisian hospitals, and by which seven patients lost their lives. The case related in this paper illustrates very strongly the beneficial effects of ammonia or its carbonate, in consequence of its stimulant powers. Chlorine, which decomposes the poison, most probably also effects a good deal by its stimulant action. Chlorine water, the most manageable form in which this agent can be applied, is rarely at hand; at present, however, chloride of lime, or soda, is as likely to be easily procured as any other medicine, and either of these can be made to evolve its chlorine rapidly by the addition of vinegar, or any of the ordinary acids. Very possibly after the patient has been to a certain degree restored by the use of these antidotes, his recovery might be promoted by an emetic, and for this purpose the sulphate of zinc, mixed with some stimulant fluid, as wine, or brandy and water, would be most suitable, as less liable to produce depressing effects, than some other medicines of the same class.

I add a few particulars of the dissection of a case which terminated fatally:—A schoolmaster of Dublin purchased an ounce of the medicinal acid (Scheele's), and swallowed it. Next morning he was found dead. The stomach in particular exhaled strongly the smell of the poison. The only morbid appearance of note discovered, was a patch of dark-red extravasation under the mucous membrane of the stomach, near the pylorus; an appearance which seems to have been mistaken for gangrene, in a case related by Hufeland. This appearance I should conceive to be allied to the black warty extravasation observed in cases of irritant poisoning. The stomach exhaled the odour for three days, at the end of which time the poison was detected by the usual means.—(Condensed from the *Dublin Journal*, Nov., 1835.)

PULSATION IN VEINS OF THE ARMS.

By CHARLES BENSON, M.D., Surgeon of the City of Dublin Hospital.

MARY OLIVER, æt. 60, of middle stature pale, and emaciated, was admitted into the above hospital on the 14th of August, 1835. She could only describe that "it was all about her heart." The following notes were taken as soon as she was placed in bed:—Incoherent, very restless, uneasy in every position; pulse 80, soft and regular; tongue clean; eyes clear; skin natural. On placing the fingers lightly over the apex of the heart, a sensation is communicated to them not unlike that which empty semina of the cellular tissue would occasion but it is lost on the least increase of pressure. Resonance very dull over the whole of the precordial region; impulse considerable as high as the clavicles, and peculiarly strong in the epigastrium; a loud bellow-murmur over all the region of the heart sometimes with a rasping noise; the latter is best heard in the second sound, the former in the first; vesicular respiration every where distinct.

Aug. 15. She became comatose last night and has not since spoken.

While feeling her pulse, I was struck with an appearance of pulsation in a vein on the back of the hand. Further examination showed a distinct pulsation in every superficial vein of the two upper extremities, but I could not feel it. Some of the pupils, however, assured me they felt it. The pulsation was isochronous with that of the radial artery, but a little later, following it after an interval of time, which, when carefully attended to, could be satisfactorily appreciated. I could learn very little of this woman's previous history, though I sent an intelligent pupil to her late residence. He could only ascertain that for the last six months she had suffered very much from palpitations and headaches; that she was often intoxicated, and had often received wounds on the head, and followed her usual occupation (selling fruit) until a few days before; and that she was a Scotchwoman.

In the evening I took ten ounces of blood from her arm, and was surprised to find that it did not come *per saltum*, although pulsation was observed in some of the veins below the bandage. The veins, after the bleeding, seemed much more diminished in size than I expected from the quantity of blood drawn off, and all pulsation ceased! This last circumstance disappointed me, as some medical friends had advised me to visit her next morning, as she was decidedly stupid, and the pulse was multuous.

DURATION OF PHTHISIS.—Of 114 cases, observed by LEWIS, rather more than two-tenths died between the first and sixth months of the disease; four-tenths between the sixth and twelfth months; rather less than a fourth between the first and second years; and less than one-fifth between the second and twentieth.

16. Still comatose, but is very sensible to stimuli. The veins are collapsed, and totally devoid of pulsation. Pulse in the radial artery 80; 90 when roused; heart's action as at first report.

19. Very little alteration, until this morning, when her left arm and leg were found to be flexed, and somewhat rigid. The veins had resumed their distended appearance, and pulsation was distinctly visible in all as it first. My colleagues and the hospital pupils now joined me in observing the pulsations. The veins rose and fell with the respiration, becoming turgid towards the end of expiration, and flaccid when inspiration was nearly complete. In both states, however, their pulsation went on regularly, beating as often as the artery, 80 in a minute, but a little after it. There was no doubt of this, though the interval was very minute. No change in the cardiac symptoms. The question as to the cause of the curious phenomena before us was now considered, and the discussion induced us to note more particularly the circumstances of the case. Two opinions were supported: 1st, that the pulsation was derived from the left side of the heart, sending on its blood through the capillaries into the veins; 2nd, that it was derived from the right side of the heart, and depended on regurgitation.

20. As blood-letting had benefited the patient before, a few ounces more were taken. It flowed distinctly *per saltum*, arterial in colour, but much thinner. The cephalic vein near the bend of the arm was selected, in order that it might not be influenced by any artery. After the removal of eight ounces the pulsation ceased. No motion in the veins of either extremity could afterwards be seen. She died on the following night.

Autopsy twelve hours after death.

The lungs almost universally connected to the costal parietes by old adhesions. No fluid in the pleura. The lungs quite free from disease; not even congested. The heart was at least twice the usual size. The auricular appendages, especially the left, were remarkably large. The right auricle was dilated, and a little hypertrophied. The right auriculo-ventricular opening was very large and gaping. The right ventricle was dilated and hypertrophied. Its cavity was twice as large, and its walls twice as thick as usual. The floating margins of the tricuspid valves were thickened, and studded with small cartilaginous nodules. The pulmonary artery valves somewhat thickened, and the corpora sesamoidea much developed. The left auricle was enlarged, and the lining membrane was thick and opaque. The left ventricle was dilated and hypertrophied; it was an

irregular slit-like opening, surrounded with cartilaginous and osseous deposits. The left ventricle was dilated, its walls a little thickened, but softer and paler than those of the right. The mitral valves contained calcareous and cartilaginous deposits. The aortic valves were greatly thickened, and filled with osseous matter. The aorta too had osseous deposits. Careful examination evinced nothing peculiar elsewhere in the whole body and vessels. One of the arms removed from the body was carefully injected from the brachial artery, but not a particle of injection passed into the veins. The valves of the latter also resisted the passage of a fluid from a trunk to its branches.

I think the *post-mortem* decided the question as to the cause of the venous pulsation. It is to the right ventricle that we must look for the efficient cause. This ventricle we find hypertrophied, and the auriculo-ventricular opening dilated; so that regurgitation into the auricle was inevitable; and as this would occur with considerable force, it is easy to conceive how the impulse would be communicated along the dilated veins, even to their small ramifications. The valves intercepted the shock when the veins were flaccid; but in the distended state of the vessels the shock was sent from valve to valve, even by the very force with which they were thrown across their tubes. And this may be supposed to take place without any imperfection in the valves, which seemed quite sound. The pulsation following that of the arteries, may be explained by the more yielding structure of the veins, which would, doubtless, retard the rate at which the impulse was transmitted.

Venous pulsation has very rarely been observed to extend beyond the jugulars. Homberg (1704) mentions a case in which the pulsation in the veins did not correspond in frequency to that of the arteries; that it was only to be observed during paroxysms of asthma; and that the *post-mortem* exhibited great dilatation of all the cavities of the heart, with thinning of their parietes, and large polypi extending from the ventricles into some branches of the aorta and pulmonary arteries. He attributes the pulsation in the veins to regurgitation during the morbid palpitations of the heart, whilst the arterial pulse was occasioned by the regular action of the ventricle. Dr. Elliotson mentions a young lady with violent cough, in whom all the veins of the back of the hands and forearms distinctly pulsated synchronously with the arteries. This is all he says. Dr. Ward relates the case of a debilitated woman in whose hands and arms venous pulsation was observed for three days, but as the woman recovered there was no opportunity of determining the cause. Dr. Davis relates a case in which the only morbid appearance discovered on dissection was, that the left

ventricle was somewhat enlarged and firmer than natural. Dr. Graves mentions two cases of venous pulsation; but he gives no details, nor does he offer any explanation of their cause. I do not think that either of the foregoing cases affords any *proof* that it depended either on the force of the left ventricle, transmitted through the capillaries, or on any independent action in the veins themselves. All the arguments in favour of either of these opinions might have been, and indeed were, advanced in the case which I have related. And yet the *disease* proved, I think, incontestably, that hypertrophy with dilatation of the right ventricle, was the true cause.—*Ibid.*

NEW TREATMENT OF CROUP.

By Dr. Kirby, Prof. of Med. in the R. C. S. in Ireland.

THE attention of the profession has been very properly directed to a new method of treating croup, pursued by Dr. Lehman, Staff-Surgeon at Torgau, consisting in the application of hot water to the region of the larynx, at the commencement of the disease. Dr. Lehman affirms that it has not yet failed in his hands when seasonably applied, and that it had been used successfully in several families, before his assistance could be procured. My own personal experience for nearly twenty years in the efficacy of a somewhat similar plan gives me the greatest confidence in his report, and I am encouraged to lay before the profession the treatment I recommend during the first hours of an attack of croup. I believe there is a disposition to this disease in the children of certain families; and when one suffers, I think it prudent to examine the other members of the group, and advise such precaution as circumstances may suggest.

My first advice is, that the neck shall be surrounded with a flannel bolster of hot salt, quickly heated to a temperature of which the hand is impatient. A woollen stocking will do, not too tightly stuffed, to accommodate itself to the form of the parts with which it is to lie in contact. This remedy acts as a rubefacient, and much beyond the limits of its contact. The face and thorax soon become florid. The temperature of the whole surface of the trunk and extremities is soon increased, and the pulse is accelerated, with a fulness and softness which promise a copious perspiration; and when that is established, it is astonishing to witness the rapidity with which the uneasiness about the larynx, the almost pathognomic cough, and the embarrassment of respiration, disappear. A triumph over the disease has now been obtained, but the remedy is to be renewed, to confirm the ad-

vantage. Tepid drinks should also be given, and even small quantities of cold water, which is exceedingly grateful, and eagerly wished for. The medicine I uniformly prescribe is a mixture of ammonia, saturated with vinegar or lemon-juice, and a few drops of laudanum, the doses of which I alternate with two-grain doses of calomel and James's powder. Diaphoresis may thus be continued for twelve hours. It may then be allowed to subside, by changing the application less frequently, and employing a lower temperature. But these remedies should not wholly be laid aside for two or three days, or even for more, should there be any cough, or the slightest trace of preternatural laryngeal sound. While the perspiration continues, I do not risk its suppression by purgatives; but when it has nearly ceased, I administer tincture of jalap, magnesia calcined, electuary of scammony, and water. This combination agrees well with the stomach, acts in small doses, and its operation is more certain than any other medicine I am acquainted with. The discharges are sufficiently abundant, and the whole business is soon at an end. The cough, which sometimes continues for a few days, appears to me to be best treated by low diet and mucilaginous mixtures, to which squill, hippo, and laudanum, are sometimes added with much advantage.

The annotator on Dr. Lehman's mode of practice advises the instant *abstraction of blood* from one or both arms, or from the jugular vein. Now, I am quite aware of the value of the abstraction of blood under certain circumstances, but experience assures me that it may frustrate the secretion of perspiration, which should be perfect; and I believe that it not uncommonly disturbs an important curative function in sudden diseases of the respiratory apparatus.

If the means I advocate disappoint expectation, and the lungs participate in the disease, the attendant distress will be alleviated by a full bleeding, and the skin may probably be thus brought into a state of diaphoresis. I remember a remarkable instance to the point. A fine child of seven years of age, and of unusual obesity, suffered from the highest inflammatory stage of croup, when I was called to perform venesection, which had been several times attempted by the persons in attendance. In a patient of so great corpulency, I doubted my success, and therefore opened an artery on the instep. Diaphoresis soon followed, and the alarming symptoms rapidly disappeared.

Emetic tartar being mentioned by the notator as a remedy to be used in venesection, I cannot close without an expression of my dissent. It withholds a thin moisture

the result of its depressing influence. *Leeches and blisters* are often the resource of men who pursue a practice of routine. I have never seen these means decidedly useful. I have known leeches to be prescribed in such ill-judged numbers that the child died of hemorrhage almost before they were disengaged. The delay in the action of a blister is an insuperable objection to it. The value of a counter-irritant is strongly displayed in the following case. A boy aged two years was brought to the hospital in the most unpromising stage of croup. I said I had no hope, but I would try an experiment. I applied a piece of *lapis infernalis*, extensively to the back of the neck, as if I designed to establish a large issue. The boy was quickly relieved, and rapidly recovered. *Mercury* is a remedy upon which reliance cannot be reposed. To wait for its effects is to waste time. In conclusion I shall observe, that I never saw a case in a child, of twelve hours' duration, which did not resist all the usual remedies of routine. It is high time to pass from a fruitless track into a new course. That, however, which I recommend is suited only to the period of invasion.—*Ibid.*

WESTMINSTER MEDICAL SOCIETY.

Saturday, October 24, 1835.

Dr. ADDISON, President.

THE balloting box was kept open until a quarter before ten o'clock this evening, for the election of new officers, when a scrutiny was taken, and the following members declared to be elected:—Mr. Richard Quann, Junior President; Mr. F. Hale Thompson, Vice-President; and Messrs. Costello, Dobson, Grilith, H. Johnson, Horne, Laycock, Streeter, Wade, Winslow, and Dr. Ryan, Members of the Committee.

URETHOTOMY AND CYSTOTOMY.

MR. COSTELLO opened the discussion, by relating the case of a child seven years of age, the offspring of a soldier, who he had been requested to see during the past week at Canterbury, who had a stone in the urethra, and one in the bladder. The nature of the case had previously been overlooked, and he now decided that not lithotomy but lithotomy ought to be adopted, and accordingly performed. The mode as regards the line of incision, on the rule laid down in his works, the first incision was nearer to the urethra. Three stones were found, the largest measuring one

inch and a half in length. Mr. Costello then made some remarks on the anatomy of the parts concerned in the operation, which we shall postpone to another occasion. The child slept well the first night, and was proceeding satisfactorily.

THE PRESIDENT requested to know, whether the bladder was much thickened; and, also, whether, in adults, Mr. Costello had found that the degree of thickening was proportionate to the straining which calculous patients make.

MR. COSTELLO replied, that he did not believe that the bladder was prone to thicken, prior to puberty; no doubt, however, violent efforts of straining were a cause of thickening.

MR. HORNE asked, in what condition the bladder usually presented itself, when the calculi were found situated in the kidneys.

MR. COSTELLO presumed that this depended on the fact of that viscus remaining quiescent or active during the renal affection.

DR. ADDISON alluded to two cases, which were designated cases of "irritable bladder;" where the sufferings experienced from the bladder during life were most excruciating; although, after death the bladder was found to be healthy, and a stannous diathesis affecting the whole substance of the kidneys, was discovered.

DR. RYAN requested to know from Mr. Costello, what was the earliest stage at which he would recommend the breaking down of the stones in children, and what was the earliest period at which he had found diseases of the prostate gland in adults, connected with stone, as he believed these to be contested points.

MR. COSTELLO answered, that the youngest advisable age was four years; he had performed it on a child at seven years of age, and numerous cases were on record at the ages of eleven, twelve, and fourteen years; but he believed that the operation of lithotomy was more easily to be accomplished, and attended with less pain in children, than that of lithotomy. As to the earliest period of life at which he had met with diseases of the prostate gland, he could say that in his own practice he had not met with it in any patient under thirty-five years of age; and oftentimes he was confident that when that gland was supposed to be affected in persons below that age, the symptoms depended on other causes; nor had he found that this disease was recognisable through the rectum in patients under forty-five years of age; for as life advanced, the prostate became firmer and of a denser structure.

DR. RYAN said he was aware that an enlargement of the prostate gland was the "condition of old age," as surgical writers termed it. He would next ask if Mr. Costello had tried in these cases the use of iodine. He had himself, in two cases, afforded consider-

able relief, especially to one sufferer, who had been discharged from our public hospitals without deriving the least benefit from the measures there adopted; and who, although the gland was very much enlarged, obtained ease from the disease very rapidly; and no doubt the cure would have been complete had the patient, who was very poor, and resided a long distance from the infirmary, been able to continue his attendance. He believed that the injection of iodine into the bladder, thereby carrying the substance into immediate contact with the gland, would produce much benefit.

Mr. CASTELLO regarded iodine as beneficial in cases of simple engorgement; but equal benefit would result from scarifying the gland. He would remind the doctor that the cavity of the bladder, although it was lined with a mucous surface, had not the power of absorbing injections; in proof of which he would state, that if one grain of opium in solution were injected into the rectum, it would produce more effect than twenty grains thrown into the bladder. He therefore considered that advantage would not be derived from the use of iodine injected into the latter cavity.

Dr. LEONARD STEWART was desirous of learning what had been the result of passing a continual stream of fluid in and out of the bladder, while the patient was lying in bed, by means of a peculiar apparatus, in cases of mucous discharges from the bladder. (See LANCET, No. 632, p. 851.)

Mr. CASTELLO answered, that whether demulcent fluids, or an alkaline solution prepared with the liquor potassæ and distilled water, were employed, great benefit was the result in cases of catarrh of the bladder affecting persons of advanced age, which scarcely admitted even of palliation by any other kind of treatment. The mode of using the instrument, and its construction, were described, but as Mr. C. considered that it would be better understood by seeing it, he promised to show one to the members at the next meeting.

Some further remarks were made on the therapeutic powers of iodine in the treatment of diseases, and then the Society adjourned.

LONDON MEDICAL SOCIETY.

Monday, October 19, 1835.

Dr. WHITING, President.

ABDOMINAL TUMOURS.

THIS Society commenced its meetings for the winter on the first Monday of the present month; the 19th, however, being the first day of which we are enabled to report proceedings. On the previous Monday evening a case had been related by Dr.

WHITING which was regarded as one of so much interest, that an opportunity was afforded, we believe, to the members to pay the patient, a young woman named Martha Collard, a visit. Dr. Johnson, it appeared, had availed himself of the occasion; and the report before us of his statements, and the discussion which ensued, runs thus, from which must be gleaned the particulars that are necessary to a general knowledge of Dr. Whiting's account.

Dr. JOHNSON said he had found the young woman to be very respectable in her station, and communicative. On examining her person he discovered, deeply buried in the cavity of the abdomen, a large and prominent tumour, slightly moveable, and evidently containing fluid, with three or four other tumours, less distinct and prominent, all containing fluid, of various degrees of consistence, and reaching down into the pelvis. Their origin was obscure, and the fact was uncertain whether they sprung from above, or (though more probably) from the liver, perhaps connected with the ovary. They were of the hydatid species, and pressed all the abdominal viscera far out of their natural situations. To an operation for their removal he could not agree,—although, while professing physic, he had some claims to a knowledge of surgery,—and at the present moment he should refuse to assent even to the evacuation of the fluid, unless it was designed that the patient should perish on the table; but he had no doubt that the time was approaching when the centre tumour should be punctured with a trocar. Some persons maintained that an hydatid tumour situated under the pectoral muscle was similar in character to these, and that the latter might be interfered with as well as the former; but he (Dr. J.) maintained that there was a very great difference between a tumour situated external to the pleura or the peritoneum, or within either of those cavities, for, in the latter case, should the contents of the tumour escape into the cavities, pleuritis or peritonitis would assuredly result.

Mr. PILCHER, under whose care Martha Collard was placed conjointly with Dr. Whiting, agreed that whatever propriety there might have seemed some months ago, when the chief tumour was less prominent, and did not fluctuate, in removing it, he was satisfied that if now attempted she would die; but still if she and her friends particularly wished it, he would have no objection to use the knife. If guided by his own judgment, however, he would puncture the most prominent to remove its contents, or establish a drain. Since she had been a general treatment the tumour was smaller, but more prominent.

Iodine had been used, and the moving tumour was the attachment, however large

were not so extensive as was generally pre-conceived.

Dr. JOHNSON alluded to Lizars' successful removal of a gigantic abdominal tumour from a woman, where the incision could not have been less than fourteen inches in length. But where one similar operation succeeded, ninety would fail. Here the subject dropped.

●
CÆSAREAN OPERATION FOR THE REMOVAL OF A FÆTUS FOURTEEN MONTHS AFTER CONCEPTION.

Mr. HUTCHINSON read a case of uterine pregnancy, in which the fœtus was removed from the abdomen fourteen months after conception. Mrs. J., aged twenty-eight years, of an active disposition and good constitution, had been married eleven years without having children; the catamenia were regular until August 1834, when they ceased, and she believed herself to be pregnant, in which belief she was supported by her medical gentleman, who found every symptom attendant on pregnancy. From the month of September her breasts enlarged considerably, a milky fluid was secreted in abundance, and the areolæ around the nipples were strongly marked. The uterus enlarged more rapidly than is usual in the early months of pregnancy, so that by the middle of September she was of very great size. She now suffered from pains in the back and the region of the stomach, occasioning syncope from their severity. During the next month the movements of the child were felt, and it went on increasing in size. After December the child was regularly felt, and seemed to become gradually stronger. At the end of April she was seized with periodical uterine pains, attended with strong bearing down, and she then considered herself in labour, especially as the ninth month, according to her calculation, had arrived. The pains continued through the night, attended with a slight bloody discharge, and after the passage of two or three stringy substances, they gradually subsided. She suffered great inconvenience for a day or two after, from the restlessness of the child, after which the movements were no longer sensible; still, however, the abdomen continued to enlarge, and her legs became œdematous. From the latter part of May she gradually wasted, and the breasts and lower extremities fell to less than half their former dimensions, except the abdomen, which remained, as to size, stationary, but her general health suffered materially. Such was the history of the symptoms up to the 14th of June, when the patient first consulted Mr. Hutchinson. The symptoms were, however, very slight; but the pulse 100; the bowels were regular; and she suffered from a bearing down in the lower part of the back

when in the erect position, and a dreadful sense of suffocation when in the recumbent. On examination per vaginam, that canal was found to be shorter than natural, and its sides were compressed by the protrusion of a large tumour, occupying a portion of the pelvis, situated between it and the rectum, and the os uteri was indistinctly felt, the fundus appearing turned downwards and backwards, its mouth being forced up behind the pubes. On the 8th of July she was much altered for the worse, and yet more reduced; pulse 115, respiration laborious, tongue dry and furred, and the bowels constipated; constant vomiting; pain in the back; continual desire to micturate; she suffered also from frequent labour pains, and bearing down, with cramps in the legs, and her nights were restless. Dr. Ramshotton now also saw her, and after examining the tumour externally, and by the vagina, he (Dr. R.) was of opinion that the case was one of ovarian disease, and that paracentesis abdominis ought to be had recourse to. On the 12th of July the Doctor and his father met, when, from the distinct sense of fluctuation communicated to the hand, he believed that there was ascites, complicated with ovarian enlargement, and the senior physician concurred in the propriety of evacuating the fluid without loss of time. Accordingly on the 15th of July, he (Mr. Hutchinson) introduced a large-sized trocar through the linea alba, about two inches above the umbilicus, where the tumour was more prominent, when about six pints of a dark chocolate-coloured fluid escaped, possessing a disagreeable, though not a fetid odour. This operation afforded considerable and almost instantaneous relief. Dr. F. Ramshotton expressed surprise at the character of the fluid, having been previously impressed with the conviction that the fluid was contained in the peritoneal cavity. At the expiration of a fortnight a lock of fetal hair escaped through the opening in the tumour, which had not healed, and other pieces afterwards repeatedly passed through, as well as globules of oil and portions of putrid skin and membranes. A hard circumscribed tumour could now be felt through the abdominal parietes, in the left hypochondrium, evidently betokening the presence of the head of a child, and the nature of the case was then apparent to all. In September her symptoms became aggravated, and she suffered much from constitutional irritation. On the 21st of September Mr. Hutchinson proposed to remove the fetal head, to which Dr. Ramshotton objected, in consequence of the advancement of putrefaction, which would prevent an entire removal of the remaining fetal substance. After the original wound had been enlarged, the consultants not agreeing as to the propriety of extending the opening, it was deemed advisable to call in a "purr"

surgeon, who concurring with Mr. Hutchinson in his view of the case, Dr. R. acquiesced in a proposal that the child should be removed without delay. Mr. Hutchison, therefore, performed the operation, by enlarging the wound both above and downwards, to the extent of five inches, Mr. Mayo assisting, who introduced his hand, and grasped the right upper extremity, which he brought out of the wound, but the cross position of the fetus prevented its being extracted without separation with the knife at the shoulder-joint. Then followed a foot, and afterwards the trunk, but the head was too bulky to be brought away entire. The funis was divided. A portion of it with some membrane was left hanging out of the wound. On examination the placenta was found to be still adherent, and it was not removed. The wound was simply dressed and poulticed, and an opening was left in the lower portion of it, to allow the free exit of any fluid which might still remain in the cyst. The fetus was as large as an ordinary fetus at the full time of utero-gestation, and the cuticle was entire, except over the scalp. On the 24th of the month the patient had passed a good night, expressed herself as being much relieved, and appeared to be cheerful; the pulse 115, but evidently excited by the presence of the medical gentlemen; she was free from rigors or sickness, and experienced no pain in any part of the abdomen; the bladder and bowels spontaneously acted, and no medicines were prescribed. On the 25th the placenta was removed through the aperture, and had the appearance of having been macerated for a long time in water. On the 2nd of October, a slight gastric uneasiness supervened, but decreased until the 8th, when she was attacked with constant pain on the right side of the abdomen, with sympathetic fever, but tomentations and salines afforded relief from these, and since then the general symptoms have remained the same, although the countenance has decidedly improved; the discharge is occasionally feculent, but granulations have sprung up, and the wound now does not extend to more than about half an inch in length. The softness of the abdominal parietes has entirely disappeared, and the poor sufferer appears to be in a fair way of restoration to health.

The unanimous thanks of the Society were returned to Mr. Hutchinson for the detail of the case; remarks were offered upon it by several gentlemen, but these we withhold from publication in the present report, as every reason existed for expecting that others would be given at the next meeting, for at the hour of adjournment, seven or eight members were on their legs evincing anxiety to speak on the case; and it will be better to review the whole at once. One of the learned members observed,

that the various opinions formed by the medical gentlemen who attended the case, though errors in one sense of the word, were not so physically speaking; but still, although the patient was now doing well, he had his doubts of her perfect recovery, owing to the ulcerative process which had commenced in the alimentary canal, indicated by the presence of fecal matter in the discharge which issued from the wound in the abdomen.

THE LANCET.

London, Saturday, October 31, 1835.

If we were to congratulate the profession, the public, and, above all, the parents and guardians of the eight hundred children who are domiciled in the town and country establishments of *Christ's Hospital*, on the election of that candidate for the office of resident surgeon, who, from his age and manifold professional qualifications, was the best fitted to discharge the highly-important functions of the station, we should, we regret to say, offer those congratulations on an event which has not occurred.

The cause of inhumanity, of injustice, and of intrigue, have once more triumphed in a medical election; but that triumph is so tainted and tarnished with disgrace and dishonour, that it has given the last stamp to the expressive seal which is attached to the decree of fate wherein is proclaimed the downfall of our entire system of hospital and medical misgovernment. There are upwards of four hundred governors of *Christ's Hospital*,—gentlemen of affluence and elevated station in society, who have become electors through the payment of a subscription of 400*l.* each, or of 200*l.*, through being the nominees of aldermen,—who, being aldermen, have become governors *ex-officio*. These gentlemen, instead of electing Mr. PLUMBE, who has engaged in the practice during a period of his time

of pathology during upwards of twenty-six years,—who for a long period was the senior-surgeon of the Metropolitan Infirmary for Children,—and who, besides, is the well-known author of an approved work on the diseases of the skin,—these wealthy, respectable, disinterested, and discerning governors, have turned aside and spurned a practitioner thus qualified and recommended, in order that they might place in the office of resident-surgeon of the hospital, a youth of the name of THOMAS STONE, an assistant in the apothecary's shop of St. Thomas's Hospital? After such an exhibition of—we really know not what to term it,—on the part of the electors, we feel no hesitation in asserting that it is the bounden duty of Parliament to take from the governors of the whole of our medical charities, that patronage and those functions which they now enjoy and exercise in the appointment of medical officers. On the institution of a National Faculty of Medicine, the transference of the powers which, up to the present time, have, in almost all instances, been so improperly exercised by the lay governors of our institutions, to a high, an efficient, and a competent authority, would not only be a matter of easy accomplishment, but would be rendered an imperative act of duty.

Leaving corrupt and all other indefensible motives out of the question, what do we observe in the election which has just terminated? Why, the supineness alone which has been manifested by the governors, would call for and warrant the interference of the Legislature. Good God! How can such men pretend that their proceedings are influenced by motives of charity? They know that the boys in the establishment have been suffering intensely for above a quarter of a century from that scourge the ringworm. They have seen that their medical

and it not in their power to remove
 have known that hun-
 for the full
 left the hos-

pital without being educated, in consequence of the check and interruption which their scholastic pursuits received from the ravages of the contagious scourge; and yet, with a knowledge of all these distressing and painful disasters, only a fraction more than one-third of the governors attended to give their votes at the election, and, strange to remark, the favoured candidate is a youth of twenty-four, and the second on the list is a youth of twenty-three years of age.

On what principle, then, did they proceed in the contest? Really we are compelled to state, and it is with pain that we place such an allegation upon record, that the governors appear to us to have been influenced by every motive and consideration, save and except that of feeling the slightest interest in the welfare of the children who are committed to their charge. Only a hundred and fifty-seven votes were given on the occasion: yet there were ten candidates, every one of whom had some supporters,—the winner who gained the victory in this extraordinary contest, obtaining only thirty-nine votes. Three or four of the candidates had ten and twelve votes. Others had seventeen and eighteen, and so on; indicating in every instance the exact force of that degree of *private family interest* which could be employed in their favour. The circumstances, taken altogether, on being presented to the public view, render it a most lamentable and disgraceful exhibition. If the governors will but examine the oath which they take on being admitted to the hospital, they will scarcely contend that they do not falsify the spirit of that oath, if the whole of their official conduct be not regulated by an earnest desire to employ the funds of the hospital to the greatest advantage for the children. The terms of their oath are calculated to nullify every feeling of self-interest on the part of the governors. The obligation, in fact, enjoins, directly, the most conscientious and scrupulous discharge of their duty. In connexion with that sacred injunction, therefore, voluntarily undertaken,

let us set before the public, and the parents and guardians of the children in *Christ's Hospital*, the words of Sir PETER LAURIE, an alderman and magistrate of the City of London, and one of the governors of *Christ's Hospital*. Let us take the words of this occupant of the judgment-seat,—of this manager of a great public charity, and by those words let us test the conduct, the disinterested and benevolent conduct, of his brother voters. We shall give his words in a dialogue which occurred between Sir PETER and one of the candidates:—

CANDIDATE. — Sir Peter, my name is ———, and I have taken the liberty of calling to solicit the honour of your support in the election which is about to take place for the office of resident-surgeon in *Christ's Hospital*.

Sir PETER LAURIE. — Your name is familiar to me, sir, but I am sorry to say that my vote is engaged.

CANDIDATE. — If it were not taking too great a liberty, Sir Peter, would you, as I am anxious to ascertain the relative strength of my opponents, state to whom your vote is promised.

Sir PETER. — Oh certainly. To Mr. ———. CANDIDATE. — Indeed! I really had hoped that my qualifications for the office would have been preferred to those of a youth who is not yet out of his pupillage in an hospital.

Sir PETER. — I admit the propriety of your observations, *but to tell you the truth, the father of the young gentleman has served me on several occasions, and I felt, on being canvassed, that I could not do less than promise my vote to his son.*

What chance has merit in an electoral contest when motives such as these can influence the conduct of the voters? Sir PETER LAURIE, on examination and reflection, must perceive that if he had sold his vote for one hundred pounds, the tendency of such sale could not have operated with worse effect on the interests of the children in *Christ's Hospital*, than his having attempted to place over them a person, merely because the father of that individual had rendered him a personal service. It was right, of course, that he should feel grateful to his benefactor; but why make other parties pay the cost of his gratitude? The poor children, and not Sir PETER

LAURIE, are now called upon to make, possibly, a sacrifice of their health, and of many, if not of the whole, of their worldly interests, on account of benefits which were conferred on the *ex-officio* governor. Even the ballot, powerful shield as it is against corruption, furnishes no security for talent or honesty, when men choose to be governed in their conduct by such motives as have been exemplified in the behaviour of Sir PETER LAURIE. At any rate the worthy knight was frank. He stated *why* he gave his vote to the youthful and inexperienced candidate. There was no disguise about him, and instead of attempting to justify his conduct, he offered an apology for his vote,—the only excuse which the circumstances could seem to warrant. The father of the candidate had served Sir PETER LAURIE, and therefore the vote was given for the son. The health, the happiness, and the well-being of thousands of children, for many years to come, were items so trifling, insignificant, and unimportant, in this affair, they were not deemed worthy of being taken into account. Still, *Christ's Hospital* is a "charity," and the governors of that institution, we suppose, must all be regarded as *charitable* men.

Gloomy as is the picture which this disclosure presents to the view of the moralist, yet it contains one point of relief. THOMAS STONE was not an assistant dispenser in the apothecary's shop of *St. Bartholomew's Hospital*. The VINCENTS, the STANLEYS, the LAWRENCEs, the HURs, the LLOYDs, and the EARLES, have been defeated in their attempt to plant another of their nominees in the medical office of the neighbouring establishment. In preferring the assistant-apothecary of *St. Thomas's Hospital* to persons who were recommended by the medical officers of *St. Bartholomew's Hospital*, some, at least, of the governor have proved that they were not ignorant of the incapacity of the magnates of *St. Bartholomew's* to wage a successful campaign against

enemy as the ringworm. A new officer, therefore, is selected, from another establishment, and let us hope that the improved system of diet and treatment which was recommended by Mr. PLUMBE when he was consulted by the Special Committee, will not be disturbed by Mr. THOMAS STONE.

But some sad misgivings oppress our thoughts on this subject. We fear, indeed, that the assistant-apothecary of *St. Thomas's Hospital* was chosen by King HARRISON and his brother treasurers, because the youth has shown that he is endowed with that pliability of disposition which will always render him subservient to the word of command in the office of apothecary to *Christ's Hospital*. Such a quality of mind was held, we believe, by the majority of voters on this occasion, as infinitely to be preferred to a knowledge of the diseases of children,—a supposition which received some show of confirmation from the fact, that Mr. ESEBIE'S LLOYD had threatened to resign his office if Mr. PLUMBE should be called upon to discharge the duties of resident surgeon. The importance of this threat may be estimated by the *governors*, as, also, may be the value of Mr. LLOYD'S services; though, for ourselves, we are utterly at a loss to understand the weight of either the one or the other, more especially after having observed the miserable figure which Mr. LLOYD has cut in his ten-year fight against the ringworm. Fortunately, then, as the *assistant dispenser* of *St. Thomas's Hospital* is elected to the office of resident surgeon in *Christ's Hospital*, Mr. LLOYD will not carry his threat into execution. He will *not* resign the office of visiting or consulting-surgeon, which is a subject of congratulation for posterity.

We cannot conclude this subject, and take our leave, for the present, of the *Governors* of *St. Thomas's Hospital*, without expressing our regret that those *Ministers* of the *Parliament* who have the presentation of the *Medical Officers* to the *Commons*,

from Mr. TARBUTT, one of the *Governors* of the hospital, that not one of the royal or endowed hospitals or charitable establishments of this metropolis, should be excluded from the operation of the new *Charity Commission Inquiry*. Since the year 1816, whenever the Act for reviving the Commission was renewed, it was always managed in the exemption clause, to provide that the affairs of certain of the hospitals should not be made the subject of investigation. In the Act which passed the Legislature at the close of the last session, and in which measure it is ordered that the inquiry into the whole of the remaining institutions shall terminate in, or before the commencement of, the month of March 1837,—only seventeen months from the hour in which we write,—no such nefarious exception was allowed to be introduced. Even in some of the institutions where the inquiry was not pushed so far as the demands of public justice required, it will be renewed and prosecuted with the utmost vigour. The pecuniary and other concerns of *Christ's*, *St. Bartholomew's*, *St. Thomas's*, and *Guy's Hospitals*, will soon be subjected to a scrutiny which cannot be concluded without advancing the best interests of those great national institutions. Had there been less of jabbing in some of those establishments, less of corruption in electing their medical and other officers, they might again have been included in the exemption clause of the new *Charity Commission Act*; but as their abuses had become too manifest and odious to be defended, they are committed, without restriction or complaint, to the scrutinizing researches of the Commissioners appointed by an executive government, the members of which are pledged to promote and support the cause of national medical reform.

IN placing the letter of Mr. RUMSEY (page 187) before the practitioners of medicine in this country, we feel called upon to express a hope that the questions which

have been proposed by that gentleman will not remain unanswered by his professional brethren. With reference to the subject of his communication we can only observe, that the proceedings which are still manifested in several of the Unions relative to medical contracts, are altogether at variance with the assurances which were given, both to the Kent deputation, and to ourselves, by the noble Lord the Secretary of State for the Home Department in the House of Commons, and by the Poor-Law Commissioners at their apartments in Somerset-House. The Commissioners contend that the Board of Guardians are at liberty to make as many contracts with medical practitioners as they may think proper, and we have every reason to believe that this allegation is strictly and faithfully correct. If, therefore, the Board of Guardians, who have a permissive authority in this instance, fail to discharge their duty in accordance with the dictates of humanity, and in compliance with the behests of the members of a most useful and honourable profession, the Poor-Law Commissioners will be called upon to interfere, and compel the parochial functionaries to obey their command, as a just punishment for their having failed to exercise a judicious authority.

We will take care that this subject shall engage the attention of the House of Commons at the commencement of the next session of Parliament, unless some effectual remedy for the grievances of which the profession and the sick poor complain, be applied in the mean time. Mr. RUMSEY, and the Committee of which he is so able a member, are entitled to the gratitude of the public and the profession, for the active part they are taking in order to remove a most serious and cruel evil.

THERE is a letter at page 188 of this week's LANCET, from Mr. W. KINGDON, in which that gentleman complains of his exclusion from the Council of the College in

Lincoln's-Inn-Fields. The members of the *junto*, the self-perpetuating clique of twenty-one, have passed over the name of Mr. W. KINGDON, in the list of members who are "eligible" for seats amongst them. In being thus insulted Mr. W. KINGDON has shared the fate of HUNTER and of WARDROP, of JOSHUA BROOKES and CONSTANTINE CARPUE, and some hundreds of other members of the commonalty. Be of good cheer; then, Mr. KINGDON.

We now have an accession to our ranks. There is one more reformer who we could not so have named had the Council been honest in the exercise of their discretion Mr. KINGDON being one of the "quiet and the peace-lovers," he would have remained a stranger to the exertions which reformers make for the benefit of their fellow-creatures, had he not been spurned at a moment when he hoped to be caressed. But Mr. KINGDON has altogether mistaken his position. His perceptions approach his intellect through a mist. Can his character suffer by his *exclusion* from the College? Monstrous thought! Had he been chosen by the *junto* as a fit associate for them, *then* in truth, he might have bewailed the loss of reputation in the profession. Behold the fate of WILLIAM LAWRENCE! *He* was elected. He is one of the set. *He acts* with them, he *sits* with them, he *persecutes* with them, he *prosecutes* with them. And *where* is WILLIAM LAWRENCE? He is *THERE* and *THERE* only. It is the burial-place of his reputation. No, no, Mr. KINGDON. Had you been *elected*, your character for honesty would have been lost. You now preserve your integrity, at a cost of three hundred pounds a year; and considering your high regard for the honour of your fame, you will feel and acknowledge with us that the receipt of the pounds sterling would have proved but a sorry recompense for the loss of your character for integrity.

At the great meeting of the College of Surgeons, January, 1826, KINGDON was

"*firm but respectful* remonstrance to the "heads of the College,—a *firm but respectful* remonstrance in that quarter,—a "*firm but perfectly respectful* remonstrance, "would achieve the object that the members "of the College had in view."

Before we say another word to Mr. KINGDON on the subject of his exclusion from the Council, we commend to his notice the brief speech that was delivered by him at that meeting:—

"Mr. KINGDON.—I think we had better proceed to remedy the evils we now feel, than go to evils that we know not of. It appears to me that there is great inclination on the part of those gentlemen who are at the head of the institution, to redress the evils of which we now complain. (*Loud cries of "no," and marks of disapprobation.*) Gentlemen, it has been said that each member present has a right to express his opinion with respect to the business upon which we are met; and, certainly, upon a subject like this, if he *can* by possibility have more than a right, I feel that he *has* more than a right to express his sentiments. (*"Hear, hear."*) And I do repeat that such strong resolutions, coming from such a meeting as is here, will have such a tendency on the conduct of those men at the head of the institution, that a remonstrance made to them, firm, but respectful, will procure a redress of our grievances. A firm, but respectful remonstrance in that quarter will have the effect of remedying the evils complained of. (*Applause and disapprobation.*) And I beg of those gentlemen to consider well how they hastily throw off from themselves their present charter, for, if they let it slip from them, they may get that which will interfere with them a great deal more; and I cannot help thinking that the objects of the profession will be best promoted by their doing that which this meeting seems inclined they should do, and which a respectful remonstrance will have the effect of procuring."

What say you now, Mr. KINGDON? Was a "*remonstrance*" the appropriate remedy? Really we are anxious to know what you would have said of the conduct of the College, or of the constitution of the Council, if you had been chosen one of the Council-

—if (that is), by your premeditated

"you had been enabled to pocket

per annum of the

M. LAWRENCE

must hold...ence on this

subject with your "hats off," and a report of the proceedings at the conference shall appear in the pages of THE LANCET, for the benefit of the uninitiated members of the profession.

A CORRESPONDENT informs us that some blockhead of a lecturer has been accusing this Journal of being influenced by its selection of articles for insertion in its pages, by the tender of pecuniary bribes. As the writer has promised to send us the passage *in print*, we shall refrain from saying more on the subject until we see the specific charge. Accusations of such a character, however, are by no means unacceptable. Every ass thinks his own bray the best, and if his paper be not received, attempts to account for it to his friends by saying that "his "purse is not long enough to ensure the "insertion of his communications."

We rely on the performance of the promise of our correspondent.

QUESTIONS

RELATIVE TO MEDICAL ARRANGEMENTS UNDER THE

POOR-LAW AMENDMENT ACT.

To the Editor of THE LANCET.

Sir,—At the last anniversary of the *Provincial Medical and Surgical Association* at Oxford, a committee was appointed to consider and report on the best means of affording medical relief to the sick poor, especially with reference to the Poor-Law Amendment Act.

As Secretary to this Committee, I am desired to solicit you to further their objects by inserting the present communication, and by supporting it with such arguments as your own just views of the subject may suggest.

The lamentable effects of recent measures, both on the sick poor and on the medical profession, and the determined attempt to *continue* and to *justify* them, evinced by the last report of the Poor-Law Commissioners (dated August 8th, 1835), demand the most decided and manly conduct on the part of the profession. Our opposition will, however, possess but little *moral* force, if it

be not supported by substantial *reasons*, and these reasons can only be deduced from a correct and ample compilation of *facts*, which, unfortunately, exist in such profusion where the new law has been carried into effect.

These considerations will, we trust, induce our professional brethren, residing in those parts of the kingdom already under the operation of the Poor-law Amendment Act, to supply us largely with answers to the subjoined queries. By so doing, the labours of this committee will be rendered more efficient, and it is hoped that, in consequence, a more suitable, a more just, and a more humane system of parochial medical relief will be adopted. I am, Sir, your obedient servant,

H. W. RUMSEY,

Secretary to the Committee.

Chesham, Bucks, Oct. 26, 1835.

The subjoined questions are addressed to individual country practitioners.

1. What has been the mode of appointing and paying medical officers of parishes in your neighbourhood for the last few years?

2. Has any alteration in the above mode taken place since the introduction of the Poor-law Amendment Act?

3. Is an *equal number* of medical men provided for the poor as formerly?

4. What is the *population* or *extent* of the district or districts entrusted to the care of *one* medical officer?

5. What is the *greatest distance* of patients from the medical officer, and is that distance greater or less than it was under the old system?

6. How are *orders* for medical relief obtained in ordinary cases? and how in urgent?

7. Have "tenders" been required? and have they been furnished? and to what extent?

8. What are the amounts of the stipends? Are they fixed annual sums? or are they payments *per case*? If the latter, is any gradation, according to the *numbers* or *distance* of the patients, allowed? and is any limitation to the sum total exacted?

9. Are the *forms* of the *contracts* in any of their clauses degrading to the respectability of the profession?

10. Have there been any *instances* of distress and danger to the sick paupers, and to what *direct* causes are they attributable?

11. Are there any other particulars, bearing on any of the above questions, that occur to you as being worthy of remark?

As the prosecution of this inquiry is likely to be attended with considerable expense, it is suggested that, *on public grounds*, communications addressed to the Secretary should be post-paid.

EXCLUSION FROM THE COUNCIL OF THE LONDON COLLEGE OF SURGEONS.

To the Editor of THE LANCET.

SIR,—Will you have the goodness to grant insertion of the accompanying letter in your Journal of next Saturday, and oblige, Sir, your very obedient servant,

W. KINGDON.

2, New Bank-buildings,
Oct. 26, 1835.

TO THE MEMBERS OF THE

MEDICAL PROFESSION.

GENTLEMEN,—Having of late been treated with injustice by the *majority* of the Council of the College of Surgeons, and having learnt that he who tacitly submits to injustice becomes an instrument to his own degradation, I take this, I believe the most proper, method to protest against the measure of exclusion which has been practised towards me. Thinking that such a body would not willingly treat any one with injustice, I suspected there must have been, unknown to me, some disparaging report abroad, and therefore addressed the President and Council to inquire if, to the belief of any of them, such report existed. After some time I received an answer avoiding the question, and thus in effect admitting that if they allowed me an unsullied reputation, they dammed their own conduct. On the same showing, however, their conduct was calculated to damage my fair fame,—more valued and estimated by me, as more essential than life itself to the well-doing both present and future of myself and family. Without power to question this conduct, shielded as it is by charter, granted we may presume by a gracious sovereign, for the benefit and not the oppression of his subjects, I still have the power possessed by every English gentleman to see that my reputation do not suffer by the partial or selfish conduct of others, and it is for this reason that I now address my professional brethren. After more than twenty years of public and private practice as a surgeon in London, I must be known to some of you; and I address you to intreat that if any of you know, or think you know, anything disparaging to my character, you will have the goodness to inform me, and thus confer the greatest favour that man can confer on man; for I am conscious that any such disparagement need only to be made known, to be proved as resting on misapprehension founded on falsehood. Henceforth, my legal ineligibility to my College, the imply that I am rendered

for election. Unless erroneous information respecting me, given to the Parliamentary Committee by the then President of the College (which he afterwards made all endeavours to correct that gentlemanly feelings could prompt), has been deemed a sufficient cause to throw me out of my fair professional course; or unless my not having an interest in common with surgeons of hospitals, or a mind easily led to surrender its own views and see things as others wish, be deemed a sufficient cause, and neither of these can be supposed to influence the minds of honourable men, I must remain under the stigma of exclusion for my own demerit, did I not make this appeal to my professional brethren, so as to make known to them that on the majority of the Council rests the responsibility of having used their power unjustly. Such conduct needs only to be canvassed, for the reprobation of the right-thinking to fall on those who practise it; and I have felt it my duty to offer my character for the strictest investigation, in order that the majority of the Council may have the benefit, if anything can be found against it, as an excuse for their unprofessional and unjust conduct. It is the conduct of such men that drives the quiet and the peace-lovers to seek and enforce change. It is the conduct of such men that renders futile the best efforts of the honourable and the able to place the affairs of our country on a footing of fairness and stability. I am, gentlemen, very faithfully yours.

W. KINGDON.

ENGLISH EDITION OF LEBAUDY'S PLATES.

To the Editor.—Sir,—I was happy to find in the notice which appeared in the last number of *THE LANCET*, on the Anatomico-Chirurgical Plates of M. Lebaudy, that the only objection against the work related to the price at which it is published. By correct information as to the number of plates contained in the fasciculus sold in Paris, and considerations of the expenses necessarily attending publication in England, I feel assured that the writer of that article will soon be convinced of his mistake in estimating my profits on so exorbitant a scale, and I shall trust to the known character of your contributors in general, for a contradiction of this imputation against my character as a man of fair and honourable conduct. The fasciculus of plates published in London, of twelve plates (not English copy contains), in a wrapper, without title, is the first expense of the work, and the duty

upon them, let the writer add that of translating, printing, and putting into boards, and he will find, after defraying these expenses, that my profits are by no means exorbitant. In case, however, the writer of the notice in question have not the data for making the estimate I mention, I do not hesitate to tell him that the amount of advantage I derive from the sale of each copy of the Atlas, to the trade, is precisely three shillings. Trusting that you will do me the justice of inserting this in your next number, I remain, Sir, your obedient servant,

J. B. BAILLIERE.

219, Regent-street, 27th Oct., 1835.

WESTMINSTER HOSPITAL.

THE officials of this establishment have abandoned their old and ruinous abode in the smoky region of Petty France, and have domiciliated themselves in a spacious edifice in the broad sanctuary on the north side of Westminster Abbey. Of the architecture of this building the critics say that it is of the "Tudor collegiate style." The plan of the architects may have been laid to complete the building in that fashion, but the funds of the building committee have not been extended far enough to perfect it. The pile, as it stands, is typical of the Hot-tentot Venus, having an apron of ornament in front, with the back and sides in *puris naturalibus*. 250*l.* would have sufficed to cover the nakedness.

REMOVAL OF A LARGE MALIGNANT TUMOUR OF THE CHEEK WITH A PORTION OF THE BONES OF THE FACE.

SATURDAY last was regarded as a regular "field-day" at this institution, in consequence of the performance of the above operation. In perambulating the wards, we observed a case of scrofulous disease of the ankle-joint, one of necrosis of the tibia in a child, in which, considering the small portion of bone removal, the wound appeared to be outrageously large; there was also a case in preparation for lithotomy, and one of severe burn and scald of the left lower extremity, which was covered with large vesications, and small collections of matter were forming and burrowing under the muscles. One of these was, in the language of the surgeon, ordered to be "scratched." "Now, sir," said Mr. GUTHRIE to a pupil of St. George's Hospital who was present, "show the young gentlemen into the operating theatre; let them get on the upper seats, and leave the lower one for the old men, the white-wigs." In a few minutes the operator entered, followed by the rest of the hospital staff, amongst whom were Messrs. STANLEY and KEATE.

Previous to the operation we paid a brief visit to the patient in Queen Anne's ward, where we found a pallid female, about forty-six years of age, lying on her bed, wrapped in a flannel gown. This female was to become the subject of the proceeding.

Her name was Mary Brown, and she had been for some years a resident of Codicot, in the county of Herts. She was admitted into the hospital under the care of Mr. Guthrie, on the 8th of July, 1835, with a tumour on the right cheek. She has been married and has had fourteen children, of whom six survive, and are, apparently, unaffected with any disease. The woman herself had always enjoyed good health until the development of the present disease. She has for some years been employed in nursing, and for eighteen months previous to giving up her employment, she was occupied night and day in attending an elderly lady; but during all this time she was not conscious of, nor did other persons notice any deterioration in, her bodily health. About Michaelmas, 1834, the superior maxillary teeth of the right side began to ache, the gums became spongy, the same teeth became loose, and an offensive discharge distilled into the mouth. At the same time the cheek of the same side gradually swelled. She sought no medical advice; but of her own accord applied fomentations and other mild remedies, without deriving any beneficial result. In the course of last spring she found clots of blood descending into the mouth from the teeth, two of which fell out; afterwards the hienaspides and molars also lost their hold. The facial tumour likewise steadily increased in size, assuming a conical shape. In March last she applied at a dispensary in the country, where she was supplied with a lotion, and recommended to come to London. Soon after her admission into the Westminster Hospital, Mr. Guthrie made an incision into the apex of the tumour, for the purpose of emancipating some pus. This aperture did not close, but communicating with the sub-jacent disease, became fistulous; the fetid sanious discharge fell into the mouth more profusely, and being swallowed, produced nausea and vomiting. In this way her appetite was destroyed, and the constant lancinating pain in the tumour broke her rest. She has recently become much emaciated. The catamenia have been irregular for four years. During the last year they have appeared four times. The bowels have uniformly acted well. Since her admittance the scope of the treatment has been merely alleviatory. Some difference of opinion existed among the surgeons as to the propriety of the operation; but, it being determined in the affirmative, Mr. Guthrie made preparations for its performance.

The patient was placed in a chair, having the head supported on pillows, and kept

steady by an assistant. A vertical incision was made through the integuments, extending from just below the tendon of the orbicularis palpebrarum muscle, to about half an inch within the angle of the mouth, which divided completely the upper lip. By this incision the coronary branch of the facial artery was divided, and a little hemorrhage was produced, which however soon ceased. Another incision was carried somewhat obliquely outwards and upwards, so as to avoid the parotid duct, towards the lobe of the ear, and a rhomboidal flap of integument was then obtained, by making a third incision from the outer extremity of this to the temple. This flap was then speedily but carefully dissected, as far as the lower eyelid, from the surface of the tumour, which was thus exposed, having the remains of the zygomatic and other muscles of the face stretched over it. As the tumour had a somewhat loose connexion with the adjacent surface of the maxillary bone, and from its protuberance was likely a good deal to impede the further steps of the operation, Mr. Guthrie removed it at once, by making a few incisions around it with the scalpel. A large mass of dense scirrhous structure, of almost cartilaginous hardness, was thus removed, which proved to be the anterior paries of the antrum, and which had become the seat of this form of abnormal formation, attended with the absorption of all traces of the bony tissue. By this means the maxillary sinus was of course laid open, and its posterior wall exposed, which was found involved in a similar state of disease. Mr. Guthrie now divided the zygomatic process of the jugal bone by a stroke or two of the mallet and chisel, and by the same means separated its ascending orbital process from the external angular process of the frontal, which did not require any great degree of force, owing to the softness of the osseous tissue. In this way the bone was perfectly freed on the outer side from any attachment to surrounding parts. Directing his efforts in a similar manner to the inner side, the maxillary and palatine bones were separated from their fellows in the line of the palatine suture, by insinuating the chisel between the two front incisor teeth. An opening being made into the right nostril by piercing the cartilage of the ala nasi, the nasal bone was separated by the chisel from the nasal process of the superior maxilla, and the lachrymal bone and the orbital plate of the ethmoid were cut through with the blunt-pointed knife.

The superior maxillary nerve where it lies in the sphenopalatine fossa, having been first carefully divided with the scalpel, Mr. Guthrie, by placing his finger on the diseased mass, was enabled to ascertain its situation; and, in the anterior order of dissection, the scalpel was

necessary to remove these connexions, which as effected with considerable difficulty, in consequence of the impediment caused by the motions of the tongue. When the mass was brought away, part of the posterior angle of the diseased sinus, where it often communicates with the ethmoid cells, was found to be left behind, and required separate and rather tedious dissection, as did so part of the glandular structure of the soft palate, and the amygdalæ, which had participated in the disease; as well as a portion of the pterygoid plate. Here of course the greatest care was incumbent on the operator, from the proximity of the carotid, which he afterwards stated he was in great fear of wounding. Upon the division of the branches of the internal maxillary artery, some hemorrhage occurred, which occasioned a good deal of distress to the patient, the blood accumulating in the fauces. It was, however, expelled by the expiratory efforts, which were increased in violence as the blood accumulated. The mouths of the divided arteries very quickly contracted, very little blood being lost during the operation, and not a single ligature being required. Dr. GUTHRIE now requested Mr. WHITE to examine the surface from which the tumour and its excrescences had been removed, in order to ascertain whether any vestige of it remained behind. A little was detected at the upper and posterior angle of the cavity, most probably in the walls of the sphenoidal sinus, which being seized with a hook, was, after a little tedious dissection, removed. The bone was afterwards scraped.

The removal of the disease now being accomplished, and forty-five minutes having elapsed, the patient was allowed to rest a while, and some wine was administered. Her wet and bloody linen was removed, and she was placed in a bed which had been brought into the theatre for that purpose. The edges of the divided integuments were brought together, and retained in apposition, in the situation of the outer incision, by means of two or three stitches of interrupted suture, metallic wire being employed instead of silk; whilst the incisions in those parts of the cheek and lips which were unsupported by any subjacent bone, were closed by means of the twisted suture, about five hare-lip pins being employed. A little simple dressing was laid over the cheek, and bandage was lightly applied.

The operator was assisted by Mr. THOMSON and Mr. SOADEN.

Although the operation lasted forty-five minutes, it was borne by the patient with a noble courage. Not an exclamation of pain escaped her. Mr. WHITE, jun., and other gentlemen were present, with every assistance to aid the operation. Somebody at the time said, "A scissor!" "A knife!"

"I want something that will cut here!" "A pair of curved scissors!" "A hook!" "A blunt hook!" "A curved hook!" "Hot water here!" "A sponge!" "My little short scissors!" and sundry others (not all of them the operator's exclamations), which were occasionally varied by, "You bear it very well, my dear lady!" "It is almost done!" "By the blessing of God, my dear soul, it is nearly over!" "Give her a little wine!" "Don't go yet, STANLEY, I want you to see it quite done!" These remarks were throughout accompanied by the clanking of scalpels, knives, and scissors, in a pewter basin, close to the patient's ear, producing altogether a discord more horrible and distressing to the sufferer than we have ever witnessed before, or hope ever to witness again.

Tuesday morning, Oct. 27.—No untoward symptom has occurred since the operation. The patient slept for two hours immediately afterwards, and has since been free from restlessness or febrile excitement. She has taken nourishment, chiefly warm milk and arrow-root, and, at her desire, occasionally, small quantities of wine and water. Deglutition has been performed with very slight difficulty, and respiration not at all affected by the operation. She has taken no medicine, but it has been necessary to keep the bowels open by injection. The wound is every where uniting, the skin is sound, and round the fistulous opening in the cheek rapidly recovering its healthy appearance. There is slight tumefaction of the lids on the outer side of the orbit. The pulse has continued at 120, the same as before the operation, no variation being detected until this morning, when the beats amounted to 102, which are regular, and more sthenical. Some time after the operation, on attempting to speak, the expectorated breath distended the affected and boneless cheek in a hideous manner, but this we understand does not occur now. The patient states that she has been much easier since the amputation than she had been for some time previously.

CONVENIENT MODE OF CONTRADICTING FACTS WHICH CANNOT BE DISPROVED.—
"The Lancet and the Medical Institutions of Ireland.—We consider ourselves imperatively called upon to state, for the information of those unacquainted with Dublin, that the articles which appear from time to time in THE LANCET, respecting the profession and its institutions there, contain such gross and impudent falsehoods, that no confidence should be reposed in them. We do not state this to avert these calumnies; they have been, strange as it may appear to simple people, of singular advantage to the objects of them, but constructed as some of them

have latterly been to impose on experienced students at the approach of the medical session, we consider ourselves called on to interpose."—*Dublin Medical Journal*, Nov. 1835.

"Called upon to interpose," in order to prevent the "calumnies" from continuing any longer to be "of singular advantage to the medical institutions of Ireland!" These shallow-pated dividers of the spoil under corrupt systems of medical government should confine themselves, when speaking of medical reform, to stating something less, and proving something more, than is their custom, taking especial care, however, that they do not shoot beyond their mark, and "prove rather too much."

PROFESSOR TIEDEMANN, of Heidelberg, left London on Saturday, the 24th inst., after having spent a month in England and Scotland, where he has been collecting materials

for a great work on the nervous system. The Professor is between fifty and sixty years of age, of lofty stature, and amiable manners. While in London he sat to an artist for a portrait, which, we believe, is about to be published by Mr. Schloss of Westminster. M. CHOMEL, chief physician of the *Hôtel Dieu*, in Paris, has also been here within the present month. He visited the various metropolitans, and found one or more of them "not very clean or very decently furnished." M. JULES CLOQUET is also in London, and designs this day (Saturday, October 31st) to be present at an operation for osteo-sarcoma of the lower jaw on a male patient at *St. Bartholomew's Hospital*, to be performed by Mr. Earle.

CORRESPONDENTS.

The letters of *Fair Play*, and *A Pupil of St. Bartholomew's*, surprise us. We have never before heard, certainly have never seen, and have never had, any kind of communication from any individual of the name mentioned by our Correspondents, nor did we know that such a person as is described was an attendant at the hospital.

THE LANCET.—The two volumes of this work, consisting of fifty-two weekly Numbers, for the year 1835-36, were commenced on the 26th of September 1835, and will be concluded on the 25th of September 1836. These two volumes will contain, in addition to other interesting and invaluable matter, **REPORTS OF CASES** admitted into the great **METROPOLITAN HOSPITALS**—**REVIEWS** of all the new **ENGLISH WORKS**, and every important **FOREIGN PRODUCTION**, published within the medical year—**REPORTS OF THE DEBATES** at the chief **MEDICAL SOCIETIES** of London verbatim, **REPORTS OF CLINICAL LECTURES** delivered at the various Hospitals by the medical officers—**EDITORIAL CRITICISMS** on the most prominent medical events of the period—**Abstracts** of the original papers worthy of analysis in contemporary Medical Journals, British and Foreign—And at least **TWO COURSES OF LECTURES** on subjects of the deepest importance to practising physicians and surgeons, to be delivered by Professors who rank amongst the most celebrated physiologists and pathologists in Europe. The publication of one of the courses will be commenced in the ensuing month of November.

ST. THOMAS'S HOSPITAL.

CLINICAL LECTURE

ON THE DIAGNOSIS, PROGNOSIS, AND TREATMENT OF *DELIRIUM TREMENS.*

(Illustrated, in part, by a Case reported at page 161.)

DELIVERED BY

DR. ROOTS,

On Monday, November 2, 1835.

You may remember, gentlemen, that when I last had the pleasure of meeting you, I concluded with an avowal of my ignorance of the precise condition of the brain and nervous system in that particular disease which is called "delirium tremens."

With respect, then, to the termination of the disease. Sometimes, if the attack has been very slight, the disease will run on for three or four days, or more, the patient will fall into a profound sleep and awake comparatively well. This, however, is not a very frequent termination, when unaided by medical means. More commonly, and more especially if it be a second or a third attack, the symptoms will increase in intensity, and perhaps terminate in convulsions, of an epileptic character, occasionally, or perhaps frequently, recurring, until the patient dies; or it may terminate in apoplexy, after one or two more recurrences of these convulsive attacks. It may terminate in apoplexy, and occasionally it will terminate in mania. The latter, however, certainly is not a common termination, but still it is an occasional termination of delirium tremens.

Prognosis.—Then as regards your prognosis; if it be a first attack,—if the constitution has not been materially enfeebled, the prognosis may generally be favourable. It is more doubtful in proportion to the advanced condition of the patient. It is more doubtful if it be a second or third attack. The prognosis, as a matter of course, will be

increased if, in addition to the irritation, you find accompanying it inflammation.

Diagnosis.—Then as regards your diagnosis. This is certainly a subject of the greatest importance, because upon the correctness of your diagnosis, will depend the probability of your patient's recovery. If you should by chance mistake true delirium tremens—and I am speaking now of the true form of the disease,—and treat it upon the principles of inflammation of the brain, the chance is that you will destroy your patient's life. Well, then, the history of the case, the history of the patient's previous habits, whether he had been addicted to the abuse of spirituous liquors, or of opium; or if to neither of these, whether, having been exposed to great bodily privations and mental anxiety, the disease had supervened upon them. Next you must bear in mind, in true delirium tremens, the absence of the flushed countenance, the absence of the suffused eye, the absence of excessive heat of head, the tremor (the general tremor of the body, to a greater or less extent), the tremulous condition of the tongue, and also its moist creamy coat,—these things being considered in connection with the state of the pulse, which is perhaps at first rather slow and soft, speedily getting quick, but still soft; and, in addition to all these, the peculiar illusion of the mind—the illusion in true delirium tremens being perfectly different from that which is observed in inflammation of the brain. The patient here, it is true, is suffering under an aberration of mind, but it is that which is easily controlled. He gets out of bed, but is easily got back again; he is subdued with very little difficulty. This is not the case in delirium arising from inflammation. These are only intended as practical remarks for your observance, and as we have not time to go more deeply into the subject, I shall go at once to the treatment.

Treatment.—Now supposing you were called to a patient who was labouring under the early stage of delirium tremens, where there was no question whatever as to the nature of the disease. Your first object in such a case would be to ascertain that the bowels were sufficiently open; and to ensure that you would give him, probably, a warm

stimulating purgative, with, most probably, a small dose of calomel,—say three, four, or five grains, with two or three drachms of the tincture of senna; and if the bowels were not readily acted upon, you would give him some of the neutral salts with it. But I am quite sure you will find that *very active* purging will do no good. As a matter of course, as I have before observed, the secretions cannot be otherwise than deranged; in the existing state of the brain and nervous system, you could not expect that the secretions, under the circumstances, would be natural; and, on this account, some who have written on the disease, being aware of this depraved condition of the secretions, have strongly recommended the employment of mercury. Now I am of opinion, and that from practical observation, that it is exceedingly proper to give occasional doses of mercury, perhaps every other day, or, it may be, once in three days, for the purpose of producing the effect of what, in older times, was called an “alterative;” I think it is right to give “alterative” doses of mercury, just sufficient, perhaps, to change, in some degree, the secretions. But I do not think you would do any good,—on the contrary I am quite satisfied that you would do harm, by giving mercury, in *true* delirium tremens, in such quantities as should produce the *specific* effects of that medicine on the constitution. Now my reason for this is, that mercury, generally speaking, sets up, along with its specific action, irritation in the system. You have already excessive irritability of the brain and nervous system, therefore I would not give mercury in sufficient quantities to produce its specific effects, because I think its administration would be likely to increase the very irritability which I wished to subdue.

What, then, after all, is the indication in delirium tremens? Why, it is to allay the peculiar irritability of the brain and nervous system; to induce sleep, and afterwards to restore the secretions to their healthy character. Allay the irritability of the brain and nervous system, procure good sound sleep, and increase the patient's strength by giving moderate tonics, aided, perhaps, by stimulants, and the secretions will, in all likelihood, return to their healthy condition, without the necessity of employing the specific influence of mercury.

What, then, are the means by which we would endeavour to allay this irritability of the brain and nervous system, and procure sleep? You all know, gentlemen, that in irritation of the system generally, or in irritation of any particular part, no means with which we are acquainted are so powerful in allaying that irritation as *opium*. Then *opium* becomes, I may say, our sheet-anchor in the treatment of delirium tremens, and that must be given in doses proportioned to

the degree of irritability in each particular case, and also to the power of the individual. In slight cases, small and frequently repeated doses of the tincture of opium, or of solid opium, or of the preparations of morphia, the acetate or muriate, will be sufficient; say from ten to fifteen or twenty minims in slight cases, repeated every three or every four hours, until sleep is procured. But if the irritability is great, you must then have recourse to larger doses; in which I should say that it would be useless to commence with a dose of less than forty or fifty or even sixty minims, and I should prefer the latter, if of the tincture of opium; or from three to five grains of pure opium, or from a quarter to half a grain of the muriate or the acetate of morphia, to be repeated every four hours until sleep was procured. If you find, after the patient has taken three or four doses, that the excitement still goes on,—that there is still a want of sleep, and the same degree of irritability and illusion, and perhaps without the pulse being augmented (without there being the slightest proof of inflammatory action in the brain itself, or in the membranes of the brain), and that the delirium seems to be increased instead of diminished, then I should not hesitate to give an increased dose. For example, if I had been giving half a grain of the muriate or the acetate of morphia every four hours, and after the third dose found the irritability not allayed, having waited the proper time after the exhibition of the last dose, I should then give one dose of a grain. Observe that I say, after having waited the proper time. Now my reason for saying this, for advising you always rather to commence with a small dose at first, and to wait the effects of that—to feel your way, as it were, than to commence with the boldest dose at once, is this, that though in a great many instances you will find success attend the exhibition of the larger dose, yet it has occurred to me in two instances, and it has also been related to me by one of the best practical physicians of the present day in this town, as having occurred to him also in one or two instances, that by commencing with a dose, say of a grain of the muriate or the acetate of morphia, such an impression has been made on the brain and nervous system, that the patient has never been aroused from it; knowing, therefore, that such an effect *may* take place, it becomes our duty to exhibit opium with caution. When sleep has been procured,—and when it is procured it very generally runs on for six, seven, or eight hours,—you find that your patient awakes amazingly relieved; in some instances perfectly

The caution I have just perhaps, be best illustrated by you the following during the to see, with the most intelligent practitioners

a lady who had been ill for some time; and it was necessary, as a matter of course, though painful to her friends, to acquaint me with the cause which had brought her into the condition in which we saw her. She had unfortunately contracted a habit of drinking brandy. Now I found her suffering under true delirium tremens. There was the tremour, the quick pulse, and, being in an advanced stage, the tremour of the whole body, the tremour of the tongue, the profuse perspiration, the absence of pain and heat of the head, and there was the creamy moist tongue. The only symptom wanting to make up the disease appeared to me to be the illusion, which I could not detect, still I was satisfied that the disease was delirium tremens, and I was very nearly quitting the bed-side, with the impression that it was a peculiar case of delirium tremens, unaccompanied by illusion; but just as I was about to go, I said—"and so you have not slept any night for some time past; you did not sleep at all last night I suppose?" She replied, "How could I sleep? We had workmen in the house." This was the fact, for there were workmen about the house; but she went on to say, that one of them had attempted to get into her room at night, and that he was constantly at the door. "He packed up all the plate," she said, "and took it away with him. He has since been apprehended, and my husband is now at Bow Street, attending his examination." Now this was all told so deliberately, and appeared to me to be so natural a chain of events, that I thought it must be true, and turning to a female relative or friend who was standing at the foot of the bed, I said—"Is that really so?" The answer showed that there was not a word of truth in the statement, except what related to the fact of the workmen being about the house. The existence of illusion was now manifest enough, and I directed half a grain of muriate of morphia to be given every four hours, and that if, after the third dose had been exhibited, the irritability of the system was not allayed, a dose of a grain should, after waiting the proper time, be given. Two doses were given, but still the irritability remained, and in about an hour afterwards a dose of a grain was given, the united effects of which three doses were such, that the medical man was obliged to be fetched, when he was under the necessity of pouring down brandy and ammonia, and using constant friction to keep the patient in a state of agitation for a considerable time, in order to counteract the effect of the narcotic poison; of the narcotic, from the patient did perceive that the medical man had said, the consequence is that I have given you from the dose.

In addition to opium, cold applied to the head is another most useful remedy, either in the form of evaporating lotion, or applied in the shape of ice.

I have already stated to you my objections to mercury. I do not think that in this stage of the disease, or in this particular species of the disease, blisters are of much service, unless you imagine there is some slight degree of congestion, or of inflammatory action going on, which you are afraid to attack by depletory measures; then perhaps a blister may be used, but otherwise I should not have recourse to it.

Well, now, during this period, in conjunction with the opium, the powers may be so enfeebled and exhausted, that the exhibition of some stimulants may be proper. Now, of those, the *Materia Medica* presents a great variety; and you will find suggestions to give camphor, ether, ammonia, asafetida, valerian, and a host of others; but I don't mind making the avowal to medical men, that in a case of this kind, as regards stimulants, and especially those which come under the denomination of "antispasmodics," I have but a very sorry opinion of them. I know what a moderate quantity of wine is capable of producing; I also know what may be gained by light nutritious diet, but I confess to you that I am not quite satisfied as to the quantum of stimulating effect that may be produced by five, six, or eight grains of carbonate of ammonia repeated every six, or every four, or every three hours. Or, if the quantum of stimulus be ascertained, still I am afraid you will give it at the risk of nauseating the patient's stomach, and preventing him or her from taking that which, in the way of nutriment, you ought at the same time to administer. However, there can be no objection, though I dare say there are many who think differently from me, for those who see their way more clearly with these remedies than I do, to giving moderate quantities of carbonate of ammonia, of camphor or ether, or, if you think that it is a good stimulant, of asafetida. I confess for myself, that I should be much more inclined, if I wanted a mere stimulant, to give some good porter, or some tolerably good ale, taking that stimulus more especially to which the patient had been previously in the habit of resorting, only giving it cautiously, and watching its effect.

The food ought, as a matter of course, as I said before, to be light and nutritious,—say milk, good strong beef-tea, animal broths, and, in some instances, where the patient's stomach will bear it, I should have no objection to allow him a mutton chop, or a slice of meat, always being careful so to graduate the exhibition of stimulants, as not to produce over-excitement; if you do that, then you will get the second species of delirium tremens; you will then have

inflammation of the brain in addition to irritation.

Supposing, then, that the opium has procured sleep, after having been obliged to resort to a larger dose, I would still continue the exhibition of the opium in small quantities—that is, if I had been giving it in the form of the muriate or acetate of morphia in doses of half a grain every four hours, then having afterwards resorted to one grain, in consequence of the previous small dose not having been sufficient to procure sleep, that one grain having had the desired effect,—then, after the patient had awoken, I should continue the small dose for a certain time every four hours, the object being, as soon as the irritability of the patient was sufficiently diminished, to diminish, also, the frequency of the dose of opium. This, however, must depend upon practical observation. It is quite impossible to lay down any positive rule as to when the quantity or the frequency of opium ought to be diminished. That must depend upon the degree of irritability remaining.

Next, as regards restraint. Now, if that can by possibility be avoided, it ought not to be employed. As I before observed to you, the delirium is, generally, of that peculiarly passive character which does not require forcible restraint, and where it can be avoided it ought, because it only produces increased irritation. One or two people, generally, ought to sit at the bed-side. It is quite sufficient to persuade the patient, merely leading him back to bed, instead of confining him with a strait-jacket, as the patient was obliged to be confined who was labouring under the second species of delirium tremens, and whose case I brought before you last week.

Supposing the irritability of the brain and nervous system to have been subdued by these means, it may then become necessary to resort to some mild tonic, and perhaps some of the vegetable bitters, some quinine perhaps may be best adapted for restoring general strength to the system. It becomes also a positive duty, an unpleasant one in many instances, more especially in private practice, to represent most strongly to the patient the risk he runs by again indulging in the vicious habits which brought on this disease, for in ninety-nine cases out of a hundred, it does arise from the abuse either of spirits or of opium.

Second Species of Delirium Tremens.—(Case of Grey.)—Well, then, with respect to the treatment of the second species,—that species under which Grey was labouring. Now in such a case the treatment must, to a certain extent, be of an opposite character, and, to a certain extent, ultimately, of a combined character. He had been twice bled before he came in. He was bled, properly bled, by Mr. STONE, when he came in.

The next day, though satisfied when I first saw him that he was suffering under delirium tremens, yet I was equally satisfied that he was labouring under delirium tremens accompanied by inflammation of the brain or its membranes, or both; for I do not hesitate again to confess my inability positively to say when the brain alone is inflamed without there being any inflammation of the membranes of the brain, or when the membranes of the brain are alone inflamed without there being any actual inflammation of a portion of the brain itself. It looks very well on paper to make those distinctions, but you will find it difficult enough to make them when you come to practise. Satisfied, then, that this inflammation existed, and that a sufficient or nearly a sufficient quantity of blood had been taken, and that it would not be prudent to risk general depletion further, I did not hesitate at that time (continuing cold to the head) to direct further local depletion by taking eight ounces of blood from the occiput, and at once giving him after that (in conjunction with the mercury, — Mr. STONE having ordered him three grains of calomel every six hours, and which I then directed every four hours — half a grain of the muriate of morphia, every four hours. You saw the result of this. After the second dose of the muriate of morphia, his delirium diminished, and he obtained three hours and a half of sleep. When I saw him the next day, there appeared to be still sufficient proof of excitement about the brain or its membranes to warrant a further abstraction of blood, although I continued the muriate of morphia, and eight ounces more, therefore, were taken from the occiput. After this no further depletion, either general or local, was necessary. He went on for two or three days progressively amending and now I come to an error in my own practice. Finding so much amendment, I was willing to diminish the frequency of the exhibition of the muriate of morphia, and as he answered perfectly rationally, as there was no proof then of any inflammatory action about his head, as the tremour was lessened, and, in point of fact, as he was in every respect better, I said, "Give the muriate of morphia every eight hours instead of every four." Well, now, what was the consequence? Why, that within four and twenty hours after that, his delirium increased; he became almost unmanageable. Mr. STONE was called to him, and very properly gave him a grain of the muriate of morphia, which quieted him, and he went to sleep. This medicine was resorted to in doses of half a grain every four hours, and continued for a certain time wholly of the brain and its membranes. It was discontinued without any further depletion of the blood. Now you may

much to bad practice as by good. I candidly admit, that I ought there to have continued the muriate of morphia a day or two longer, as frequently as it was given before. You will observe, too, that there was another modification of the treatment, because with the exhibition of the opium, which is not proper, if you have merely inflammation of the brain or inflammation of the membranes, it was necessary, and speedily too, to give him some good beef tea, and in addition to the beef tea it was necessary to give him some stimulant. I confess that I did not here have recourse to musk, camphor, ammonia, or asafoetida, but to a small quantity of porter, which he bore very well, that is, his brain and nervous system bore it well, but it was not agreeable to his taste, therefore in the course of a day or two it was changed to a small quantity of wine; the wine also he did not like, and that was changed, ultimately, to a small quantity of brandy, a tablespoonful twice in the course of the four-and-twenty hours, properly diluted with sage, arrow-root, or gruel.

With respect to the exhibition of mercury, you remember that I stated to you, that in the treatment of the true disease, I myself did not believe it to be necessary, or that it would be advantageous, to give mercury so as to produce its specific effects upon the system, and I gave my reason for so thinking; but still mercury was given here. But then, here were two diseases; there was *inflammation of the brain* supervening on *delirium tremens*, and the mercury was given on the principle of its being one of the best adjuvants which can be employed in conjunction with depletion, general or local, in diminishing inflammatory action in any of the tissues of the body, excepting the mucous membrane of the bowels; that is, in my opinion; but here it was given—and I think it is probable that I should have given it myself—twenty-four hours before I saw the patient. I say I think I should have given it myself. Still you are to remember what it eventually did. It set up excessive irritation in the mucous membrane of the bowels, so that we had a harassing diarrhoea, which we were obliged to combat with astringents and doses of opium, even after the irritability of the brain and nervous system had so far subsided as to render the further exhibition of morphia unnecessary. Nay more, the mercury went on to produce something beyond irritation; so I presume, from the nature of the discharges from the bowels. Certainly there was a degree of inflammatory action set up, independent from the discharges, along the track of the intestines, and, sub-
sequently, the heat there, and, subsequently, the inflammation, and, subsequently, the convalescence from the delirium tremens. This is an effect of mercury, which

cannot always be avoided, though an effect which one does not desire, where the patient has been suffering under such a disease as that upon which I am now making my observations.

It has been suggested by some practitioners that antimony might be of service in delirium tremens, given in large doses. Upon that I have no right to offer any observation, because I have never seen the practice carried into effect; but I may take the liberty of stating what my idea is on the subject. I think that if useful at all, it can only be useful in the second species of delirium tremens, namely, that which is accompanied by inflammatory action; and that as, very frequently, the stomach in delirium tremens is so irritable as to make it an object with us to tranquilize that organ very speedily, I certainly cannot imagine antimony to be useful in the true delirium tremens. I should hesitate very much before I employed it in the second form of the disease.

It has also been stated that digitalis has been given with advantage, I think by an American physician; I am not quite certain whether it has been employed in this country; but it has been said to have been used, and in doses which excite at least my surprise,—in doses of a drachm,—of sixty minims every two, three, or four hours, frequently repeated. I only mention that such facts have been brought before the public. They may be true, but I am quite satisfied that I never should have felt warranted in employing such a remedy in most of the cases of delirium tremens which it has been my chance to meet with.

I stated to you that it was exceedingly necessary to form your diagnosis correctly with respect to delirium tremens, so as to discriminate the true delirium tremens; and it has just occurred to me that I did not allude to one circumstance which should have been mentioned. If perchance you mistake true delirium tremens, in a very shattered constitution, for inflammation of the brain, and treat it as inflammation of the brain, I stated that you will most probably lose your patient. Now, I saw an instance of that some fifteen or sixteen years ago. The case was one of a butcher, who had drunk exceedingly hard, and there was a consultation of three medical men upon his case. Of course I had not then the same degree of experience that I may be supposed to have now, but still it appeared to me to be decidedly a case of delirium tremens, and as such it was proposed to treat it. A difference of opinion, however, existed as to the remedies, and so satisfied was one individual in consultation as to his view of the matter, that he said we should certainly destroy the patient if blood was not abstracted, either generally or locally. The juniors bowed to the senior authority,

and twelve ounces of blood were directed to be taken from the occiput. Immediately upon removing the glasses the man fell into convulsions and died. Now I do not think that that result would have happened if this depletory measure had not been adopted. It might. It is impossible to say that it might not. He had not previously suffered convulsions; but I do think that the fatal termination would not have happened had the blood not been abstracted.

I am anxious, gentlemen, to recal your attention, to prevent misapprehension, to one part of the case of this man Grey. I mentioned to you that the medical gentleman who had seen him before he came into the hospital had very properly directed his feet to be put into warm water, and I added that they had indeed been put into warm water,—that they had been put into boiling water; and I am anxious just to recal the fact to your minds for the purpose of now saying that this immersion was not the act of the medical gentleman who saw him, but an error of the friends of the patient, or the people about him. The medical gentleman had no kind of intention of putting his feet into boiling water. It was the error of others, not of him.

I was about to call your attention to two cases of gastric affection that have occurred in the hospital,—one a well-marked case of chronic gastritis, and treated as such; the other of gastric irritation—one, at least, which I myself believe was not at all of an inflammatory character, though it was thought right in, some measure, at first to treat it as though it were; but as it only wants five minutes of the hour, it would be absurd now to enter into a consideration of two cases which are of considerable interest, and therefore they will occupy our time at our next meeting.

. In the lecture by Dr. Roots, published on the 31st ult., the suggestion of the term "*delirium cum tremore*" was, through misapprehension, ascribed to Dr. Copland, in whose "Dictionary of Practical Medicine" the term is, we believe, applied to the disease commonly called "*delirium tremens*." The name, however, was first employed by Dr. Elliotson in the following passage, which we extract from a lecture delivered by that gentleman in 1831:—"The disease to which I allude is called *delirium tremens*, which is rather an improper word, because the delirium cannot tremble. It would be better to say *delirium cum tremore*," &c.—ED. L.

MIDDLESEX HOSPITAL.

CLINICAL LECTURE

ON CASES OF

DISEASE OF THE SPINE,

DELIVERED BY

SIR CHARLES BELL,

On Tuesday, November 3rd, 1835.

I EXCEEDINGLY regret, gentlemen, that you are occupied so constantly,—from morning to noon, and from "noon to dewy eve,"—attending lecture after lecture on medical subjects. It is hardly possible, under these circumstances, to be a usefully diligent student, for you are apt, amidst the perplexities, to forget the great object for which you have come to London, which is to pursue the study of anatomy and surgery,—two points that will ever be well taught in London alone. A gentleman once rose in the House of Commons, and declaimed with great emotion about the danger to which his Majesty's liege subjects were liable, of being poisoned in consequence of the ignorance of boys in apothecaries' shops; when another member rose and said, that they managed those things better in Germany. And so a certain class of members of Parliament take up the matter, the Government being always glad to see the House of Commons occupied on a subject in which they incur no personal responsibility. The present principles of medical education have gone on developing themselves, until all the birds of the air have given to the Apothecaries of London, the power of deciding what lectures students shall attend, and the studies they shall pursue, and the result is that a system prevails under which no individual can do much; for it is requisite in order to accomplish the curriculum, that the lectures which you attend should be multiplied as to keep you on the move, with hardly an interval of time between them from one theatre or one lecturer to another until one is put in mind of Matthews's account of the sweepstakes, where the horse are all neck and neck together, and all come to the goal at once.

Well, now, you must consider it my duty if I am so unfortunate as to be against Companies of Apothecaries, Colleges of Physicians, Councils of Surgeons, and Parliament, to hoot, to remind you, that you are in London is to study, to learn, thoroughly anatomy, with pathology. I am sorry I shall not be able to present you to address you.

liar advantage. I formerly gave my time unwillingly to the delivery of clinical lectures, because when I looked around, I found that the pupils before me belonged to three or four different schools, with no ideas common to us all,—with no principles such as I could conceive to be correct, and, therefore, with no possibility on my part of being usefully employed in commenting on the progress of cases. Now, however, the case is different, of which I will give an example. Supposing that you were to go into Clayton's ward, where there is a man lying with a wandering mind and a bewildered stare, a very pale face, and a deep-coloured extravasation around the eyes, and grunous blood issuing from the ears. This man has fallen on the top of his head, and were I to enter upon the case in the hearing of those who were initiated in the doctrines delivered here, I should be obliged to describe the whole structure of the head, and the principles of the entire machinery on which the skull is built. But now, in half a sentence, I can say,—There is an example of the case of which I speak. There is a man with a blow received upon the upper part of the parietal bone, the effect of which is visible on the temporal bone, and in the ear. Or here, again, is a man lying with a fissure in the base of the skull. Would it not be necessary, in lecturing upon such a case, that I should go into the whole anatomical relations of the fissure. I should merely need to say, that here is an illustration of such and such facts, or principles, as I had endeavoured on a former occasion to inculcate. The same thing would avail me in a case of fracture of the humerus near its head, for instance, of which we have an example. On such an occasion I need hardly speak of the necessity of particular appliances in the treatment, such as saying, that if the lower part of the bone be not properly disposed, such and such effects will be produced by the pectoralis major and other muscles. One word will now be sufficient for those who are properly initiated, as I shall take them to be, in anatomical demonstration.

After this preface I shall beg your attention to some diseases of the spine, principally taking up that which is termed "lateral curvature." There is, amongst others in the hospital, a case of extreme curvature, with scrofulous caries of the bodies of the vertebrae; there is also a case of inflammation and scrofulous disease going on in the upper vertebrae of the spine; there is a case of irritation and spasmodic affection of the sterno-cleido-mastoides; there is a case of permanent rigidity of the sterno-cleido-mastoides; and a case of distortion of the head and shoulders. I shall now give you a better series of illustrations of these diseases, to study by yourselves, and to take advantage of the dresser's

book to read an account of the cases. The first is that of Elizabeth Millross, who was admitted so far back as April the 23rd, an indolent girl, who, like many other indolent girls, is the subject of curvature of the spine. The distortion became evident from the circumstance,—remarked by her parents,—of an awkwardness in her gait, and they now conceive that the right shoulder is "out," and so, indeed, when you take off her clothes, and expose the back, you find that the right shoulder is very prominent, that the scapula is elevated,—that there is great protuberance of the ribs and scapula. The "shoulder" in this case is not at all to blame,—but there is expansion of the ribs on the left side, in consequence of a curvature in the spine, below there is another curvature, forming the spine into the shape of an italic S, the cause of which is to be found in the following manner:—An indolent and weak girl, with a constitution disordered by the first attacks of uterine irritation, experiences a pain in the back, and suffers great weakness and languor. To relieve herself from the pain and debility, she "hangs," as they express it in the North, "upon the strong foot,"—that is, the right one, and eases the left one, the result of which is, the twisting of the spine to the right side, and the tendency to curve the whole body in a corresponding direction, but as this cannot take place, it begins to poise itself, producing a second curve in the spine, which second curve throws out the ribs. Here is an instance in a poor girl who died in this hospital from disease produced under these circumstances. The spine is seen to be first inclined to the left side, and then to the right, forming a curve the convexity of which is towards the right side, and the concavity towards the left. Thus the left ribs are drawn together, and, while the whole mass of the thorax is diminished, the right shoulder is thrown out. You thus perceive also how there comes to be an inequality in the shape and position of the pelvis,—the cause there is for the mother or the instructor to observe deformity in that part. All this is the mere result of a defective constitution,—of a constitution irritated by the first changes in the uterus, thus operating, chiefly, in consequence of habits of indolence,—from the want of that activity which I need hardly remark is essential to the strength and perfection of structure. You have an excellent opportunity of observing the truth of this in bones while they are recent. The spine consists not only of bone, but of cartilage and ligaments, with muscles going from point to point. Now the bones do not grow by themselves, nor do cartilage, ligaments, and muscles, but they all belong to one constitution, and fail or become perfect together. Therefore it is quite wrong to talk of an affection of the spine being peculiar to the vertebral bones, or to the muscles, or

the ligaments. The whole substance of the spine in such cases is debilitated, that action which is the great stimulus to its perfection having been wanting during the period of its growth. Hence the basis of health in these parts is activity, and that activity should be directed so as to counteract any tendency to curve in the spine. It must, however, be recollected, that you cannot bend the spine as you would a twig. You must persevere gradually in your attempts to make it grow in a right direction.

The next case to which I shall call your attention is that of Ann Hetchins, ætat. 20, who was admitted on the 9th of September, stating, that about a year and a half ago she was affected with pain and weakness in the loins, after which she lost the entire use of her lower extremities, and soon after was admitted into the *Salisbury Infirmary*, where she continued for six weeks, during which period various remedies were administered for her relief, issued amongst other means being applied on each side of the affected part of the back, but without producing any advantage. At present there is very little pain, and she is comparatively easy when in the recumbent posture, but when made to sit up, she complains of a sense of weight and weakness in the back. Her lower extremities have lost all power of voluntary motion, but sensation is not entirely gone. At one time she had great difficulty in passing her urine, but now that symptom is much relieved. On examining the spine there is a projection backwards of some of the last dorsal vertebrae. The catamenia appeared when she was first affected, and have not occurred since. Her general appearance (says the report) is that of a person in good health. When the extremities are moved, it is apparently without her knowledge. There is no relaxation in the abdominal muscles, no bagging of the belly, and she can tell when her feet are cold, or when cold is applied to the extremities.

Here you have the brief relation of a case of scrofulous caries of the vertebrae, with acute curve of the vertebral column. The first point to arrest your attention in this case is, the formidable contrast which is afforded in it at least to the constitutional weakness, or predisposition to the disease, which existed in the other patient. The disease here is not actually formed in what may be called a vital part. The bones of the vertebrae, especially, are of a spongy and light texture, and are proportionably liable to become the subjects of scrofulous inflammation. There is some little debate among pathologists whether the disease of the spine in these cases commences in the ligaments, in the inter-vertebral substance, — or in the bodies of the vertebrae. On dissection we find that all are affected, and it is a vain speculation to endeavour to determine which of the parts is primarily affected.

We know that the bones, the ligaments, and the cartilage, are the parts of the body most liable to scrofulous action, and in this part they are more intricately combined than elsewhere. It is stated in the history of the case that she had experienced a wrench in the back, or, at any rate, that she had been in the habit of raising heavy weights. Now it is very possible that this may have been the origin of the disease, though I do not quite agree with my friend the dresser, that the patient appears healthy. On the contrary, I should say that a distinctly scrofulous diathesis is marked in her appearance. However, this girl may, by raising weights, thus have given origin to the disease.

Here now is an illustration of the advantage of a (concentrated) school. I am able to produce you a specimen of lateral distortion of the spine, not exactly resembling the last case, but presenting an acute projection, directly backwards, formed by the wasting, ulceration, and absorption, of some of the vertebrae. Pray let this specimen make a due impression on your minds. When these facts are placed before you, I need hardly point out what is the great doctrine for practice which the opportunity of observing them points out. But to return to the case. I stated that there was pain in the loins, and this is a remarkable circumstance; yet it is one which I observe in all these cases, and the reason of it is apparent. The power of motion is entirely gone in the lower extremities, but sensation is only partially affected in them. Sometimes, however, it is entirely absent. On referring to the spinal marrow, you will find that the nerves of motion are so directed, in issuing out from the chord towards the bodies of the vertebrae — that should inflammation take place in the bodies of the vertebrae, it must affect the motor nerves at an earlier period, and to a greater extent, than those of sensation. We observe the fact, and this is the explanation that I give of its occurrence. The circumstance leads to another question. There are persons in London who profess to cure diseases of the spine, and who ridicule the regular surgeon for not attempting an effecting the cure of scrofulous caries of the vertebrae. These spine doctors "cure" the disease by raising the body and stretching the spine. Now does this suggestion offer or not a very important remedy to our notice? Ought you to adopt the same plan in similar cases? It is true that you may lead the patient to believe that you can use fully extend the length of the patient some inches, and having done so, you may report the body at that length by a tape. But what more do you do? You do not raise the surface of the spine, you do not destroy the inflamed parts, you do not destroy the whole of the ligaments, and allow

separation of the vertebræ, and there is actual caries destroying one after another of the vertebræ. Then of what use is extension of the body? I know that it is quite possible to stretch these persons, to raise them up; but what can you expect to follow that raising? There is a large gap, a vast hiatus, between the upper and the lower portions of the diseased bones, so that ankylosis cannot possibly take place between them, although it is to that very process that you must look for the union of the vertebræ, and the mending of the diseased spine. Unless then the parts be kept perfectly at rest, and in apposition, how is it possible that we can expect a cure, knowing for a certainty that a cure never did take place in any of these cases, except through the process of ankylosis? Besides the prevention of this cure, there is also the danger,—though this may be only a speculative suggestion,—of a falling down again after it is raised, and support is removed. I look with horror on the consequences of such a fall after the bones have been thus upraised by mechanical means tending to separate them. The effect of a sudden fall would be not only a new curvature, but an injury of the spinal marrow itself. What then does this quackery mean? It must be productive of great harm if the disease have not proceeded to ankylosis, though it may do *some* good when ankylosis has taken place, by twisting and moulding the upper and lower parts of the body, so as to accommodate them to the fixed position of the ankylosed portion of the column. That is all which these quacks can effect. But suppose a person to labour under this disease, the inflammation to have subsided, the ankylosis to take place, the whole mass, by the solidification of ankylosis, to be strengthened, and the quack then to begin his forcible process of stretching, hoping to do no harm by it, but endeavouring only to cause the upper and lower parts to accommodate themselves to this permanent curvature; even then it should be remarked that he goes to work with the danger of breaking up the long-established connection of the bones, or tearing asunder that union which is not yet bone but only ligament. Thus you perceive that the preliminary cure requires a state of perfect rest. On looking round the hospital, you will see hundreds of instances of disease in which I am sure I do not exaggerate, when I say that motion alone is keeping up the disease of the patient. It is so in all the joints, it is so in ulcers, which are so much trouble, and it is so in ankylosis. So long as a person is kept in this position, there can be no cure, without a corresponding change in the nature, and as there is no incessant source of irritation kept up, motion of the parts diverging from

that centre, it is your business to keep the patient in the horizontal posture, and to have the mattress so moulded to the projection of the spine, that the latter can sink into the former without injury. The patient must be so guarded, that if she moves at all, there should be no motion in the inflamed parts.

The next point for consideration is the treatment by counter-irritation, which it is asserted by some persons does no good, though I am unwilling to admit the correctness of that denial. Counter-irritation by issues may be beneficial, but the greatest portion of benefit is to be derived by attending to the origin of the disease, the defects in the constitution of the patient, and endeavouring to rally its powers to get rid of the cause.

Before I quit this subject, I must make one further remark, because I have seen it stated in a book, that there are no diseases which present a greater variety of forms than affections of the spine. This seems to me to be a very extraordinary statement; but I know how it happens; it results from persons mistaking a sympathetic affection for the real disease. When there is actual caries of the vertebræ, and an actual falling forward of the spine, the symptoms may vary in consequence of the inflammation reaching to the spinal marrow itself, or it may be attended with more or less pain, and there may be more or less paralysis. But people class together fifty different affections under the head of caries or disease of the spine. I do not, after all, however, so much wonder at this, for I can assure you that there is nothing more difficult than the diagnosis where the spine is affected. There is a languid girl, for instance, who, when she walks, has great pain in the loins, and a suspicion arises that some disease exists in the spine. You strip her, examine her, and feel down each process of the vertebræ; you come to a particular spot where there is acute pain, and you say, "Do not deceive yourself; are you *sure* that there is pain at this part?" She will repeat that she positively feels pain in that particular spinous process. Here, then, is an injury, but it is not the disease itself. The principal source of derangement, in by far the greater number of such cases, is uterine irritation. If you place her on her back, and confine her to that posture for months, you ruin the constitution. You are just doing that which excludes all hope of amendment, for amendment depends on exercise and freedom of air,—on the restoration of constitutional strength, and the return of the uterine functions. By following a course of practice not indicated by the disordered uterine action and the pain in the back, as sympathetic of the original disease, you devote the poor creature to a condition in which she lies without a chance of improve-

ment. I have raised up at least twenty young women out of this condition, when they had been from eight to sixteen months in the horizontal posture,—not labouring under disease of the spine at all, but merely suffering from sympathetic pain there, arising from other internal disorder. The original cause is sometimes in the bowels; it may be in many other of the viscera; affections even of the lungs will produce it; affections of the heart will occasion pain in the spine. Pain in the mammae, or disorder in the colon, or disease of the uterus,—all these are pregnant sources of error, producing the very symptoms which may be mistaken for carious disease of the bones of the vertebrae. These are very different cases from those in which I have before described rest to be essential to the cure.

Another case in the hospital is that of Mary Blaymer, *etat.* sixteen years, who was admitted on the 6th of October, on account of a distortion of the upper vertebrae of the neck, which throws her head towards the left shoulder. There is a tumour, extending from the occiput, of five fingers' breadth, down the spine. The third and fourth vertebrae project, but they are only obscurely felt to do so, in consequence of inflammation and hardness of the tissue surrounding the vertebrae, and occupying all the upper and back part of the neck. She cannot turn her head without pain, and the chief motion takes place at about the fifth cervical vertebra; that is, when she attempts to move the head, she turns it on probably the fifth vertebra of the neck, all the upper part of the spine being consolidated. An example of this disease is now on the table, and here is also another specimen, proving what an extraordinary defect may exist in the upper vertebrae. In the summer, says the report, she had rheumatic fever, which continued for four months, and on getting better this swelling began. She has no weakness of the arms and fingers, and never bad: there is occasionally a difficulty of swallowing, or, rather, she has had that difficulty, for it is now removed. She herself attributes the difficulty of swallowing to tension caused by the pressure of the tumour. There is an issue in the neck, and she has taken liquor potassæ, and aqua calcis. Her head is more upright now than when she came into the hospital.

The first reflection that I shall make on this case relates to the long-continued fever. On inquiring into these cases of affection of the spine, you find, for the most part, that it is such long-continued fevers and long confinement that produce this scrofulous diathesis. A course of mercury will produce the same effect. In fact, whatever reduces the power of the constitution below par, will render the patient liable to scrofulous action, from a slight injury done to any of those parts, which, I repeat, are particularly liable

to disease. This case no doubt must appear more formidable to you than the last. Inflammation in the spinal marrow is serious enough; but inflammation in the medulla oblongata, or pressure upon it, must produce instant death. There have been in the hospital some melancholy cases of sudden death resulting from fracture of the spine, and a giving way of the upper vertebrae. It is alarming to find the vertebrae so diseased as you perceive them to be in this case, for the ligaments must also partake of the disease, and therefore the bones are particularly liable to displacement. If a wrench of the neck or a displacement of the vertebrae occurs, the medulla oblongata becomes nipped, and instant death ensues. If pressure be made there,—that part of the nervous chord being the source of all the nerves of respiration—not a word is afterwards spoken, not a breath more is drawn, but death as instantly follows as if an animal had been "pithed."

We cannot, therefore, avoid being alarmed on perceiving such a mass of disease around the upper part of this patient's spine. At the same time, however, it is obvious that there is some interposition between life and the fatal event. It somewhat resembles the disease called "pole-evil" in the horse. There are ligaments connecting the horse's head to the thigh and bursa, and when he is reined up suddenly he is very liable to injure the union of the head with the spine; but, luckily, this occurs not in internal but in external parts, and gives rise to a swelling, abscess, and suppuration. This is a scrofulous disease in the pole of the horse, and I apprehend that the same kind of scrofulous disease may be set up in the human neck, by a sudden wrench, followed, perhaps, by anchylosis of the vertebrae. The disease happens, in such case, externally to the theca, which, you will remember, is very thick. You remember the ligamentum infundibuliformis, the powerful ligament, which, like a funnel, runs down from the dura-mater and occiput to the spinal marrow. It is that which affords protection in this case, and allows the girl to move her head about with a degree of fearlessness which would otherwise make me shudder to see her move at all.

As to the cure of the case, it must be conducted by paying attention to the constant fixing of the part, preventing all lateral motion, and inculcating upon the patient the necessity of avoiding all acts of violence. I hope that if this advice be attended to, time will solder the parts together, producing anchylosis, and that the girl will, as regards her life; but she will, by this, lose all motion of the imperfectly ossified vertebrae at the lower part of the spine.

I make these remarks preparatory

notice of a case which I believe will prove a source of much interest to you,—that in which a woman has an affection of the sterno-cleido mastoideus, which is a very peculiar disease, of which I have seen a great deal; and this again will lead to the mention of another case, in which there is permanent rigidity of the sterno-cleido mastoideus. I shall speak of these patients on another day, and then advert to some interesting cases of disease of the face.

ST. GEORGE'S HOSPITAL.

CLINICAL LECTURE

ON CASES OF

DISEASE OF THE HEART, DISEASE OF THE LIVER, CONTINUED FEVER, AND PALSY,

DELIVERED BY

DR. SEYMOUR,

On Saturday, October 31, 1835.

I HAVE very little to say to you, gentlemen, this afternoon. The fact is that the greater number of cases which remain for me to notice are getting well, and I have spoken of almost all of them to you in the progress of recovery; however, I shall allude to them in their present state, and then I shall speak of those cases of palsy which are in the house, the only cases of any great interest at present here, the others being in a progressive state of convalescence.

OSSIFICATION OF VALVES OF THE HEART (?)—There is a man of the name of Shepherd, of whom I spoke to you last, and who, according to my idea,—but any body may be wrong,—according to *my* idea, is labouring under a degree of ossification of the valves of the left side of the heart, without increased size of the heart, and unattended with dropsy, but it is sufficiently diseased to prevent the proper return of the blood from the lungs to the heart; hence there is extravasation of fluid into the chest, and a very irregular pulse, partly dependent on the state of the valvular apparatus, and partly on the necessary irregularities of the action of the heart in forcing on the fluid. He has been treated for inflammatory dropsy, which I am satisfied never existed.

He had all the symptoms of dropsy in the chest,—difficulty of breathing,—irregularity of the pulse,—swelling of the face,—blue-ness of the lips,—an irregularity in the circulation,—and all this without dropsy in other

parts of the body; proving that the obstruction, whatever it was, was partial, and acted more on the circulation of the blood through the lungs, than on its circulation in the other parts of the body. The blood was freely brought to the right side of the heart, but impeded in its progress to the left side of the heart. I put him on low diet, and gave the infusion of digitalis, with the oxymuriate of mercury, and the tincture of cantharides. He has made, ever since, a large quantity of water—two quarts, or more, in the course of the four-and-twenty hours. The consequence is that the startings in his sleep have been diminished—are gone, in fact; he sleeps quietly; the pulse is losing a great portion of its irregularity, is becoming full, is 84 in a minute, and the man expresses himself as being well. The *prognosis* in this case is dangerous. If the cause remain which produced the effusion into the chest, the patient will probably die suddenly.

ENLARGEMENT OF THE HEART, DILATATION OF ITS CAVITIES, ADHESION OF THE PERICARDIUM (?) FOLLOWING RHEUMATISM, WITH RENAL DISEASE.—Going, then, from that ward into Cambridge ward, there is a man of the name of Foster, who labours under dropsy—enlargement of the heart, with apparent dilatation of its cavities, and adhesion of the pericardium. He had been subject to rheumatic inflammation, which has produced the pathological condition of the heart—the uniform condition which accompanies this disease in general—the pericardium adhering to the heart. Two years elapsed from the rheumatic attack, without his suffering any inconvenience. The heart then began to dilate, and at present it is quite clear that it is so much dilated, that the valvular apparatus of the heart on the left side does not meet and fully close the cavity; hence the blood is forced out somewhat irregularly,—in gushes, as it were, and in larger streams. The pulse is larger, in this particular case, on this side of the heart than it usually is, because the valves are not closed; at least that is my explanation of it; there may be a more scientific one, but that is *my* explanation, and I am only here to teach you my own views.

The remedies employed in this case had the effect of getting rid entirely of the water. He was treated with calomel and opium in the first instance, with a view to diminish any inflammatory action that might be going on in the pericardium. He had some return of rheumatic inflammation, and he was bled. His mouth became a little sore, and I ordered him to take the nitre draught, two or three times a day, with ten drops of the tincture of squills, and a grain of opium at bedtime. The urine was not increased in quantity, and he was then ordered to rub in the squills, in ointment, which is the plan

I am now adopting in some cases, and which has appeared to me, in more cases than one, to be effectual. On the 26th he voided five quarts of urine in two days. On the 27th the anasarca appearance had disappeared. To-day there is doubt whether there is any fluid remaining at all. The heart is permanently diseased, and, consequently the prognosis is unfavourable. It does, however, occasionally, happen, that after having got rid of the fluid, and having reduced, in some degree, the inflammatory action, the patient does well, and goes on without feeling much inconvenience. At all events these are chronic cases, and admitting of great relief. This patient likewise labours under disease of the kidneys; the urine coagulates very strongly—another unfavourable prognosis. He is not able to retain his water for any length of time.

HYPERTROPHY OF THE HEART ?—A patient of the name of Ingram also labours under disease of the heart, but in a different way. He does not appear to have suffered from rheumatism, and his case is called, according to the language of the day—I will not say the *jargon* of the day, from fear of giving offence to any body,—but according to the *language* of the day, “hypertrophy of the heart.” The heart appears to be enlarged, and the walls are greater in proportion than its cavities; and it is in this way that secretion is produced and dropsy takes place. This patient's case is the reverse, in some respects, of what we saw before,—both, however, labouring under disease affecting the valves of the heart,—the one with an increased, and the other with a diminished flow of blood through them; and, consequently, in the one the pulse is small, the converse of that in which a large quantity of blood is sent out from the heart. The same thing, as to the small stream of blood to the vessels, takes place, where any obstacle to the circulation arises, as in aneurysm of the great vessels; more particularly where it appears to be aneurysm at the bifurcation of the aorta. In all those cases the disturbance in the chest is very great. I have often quoted to you, you will recollect, the case of a little boy who died here of rheumatic pericarditis, with an enormously enlarged heart. He had been four or five years the subject of the disease. He had various paroxysms before his death, and you could hear his heart beat as you went up stairs; but the pulse in that boy was always remarkably small. His heart occupied more than a third of the chest, and yet the pulse was so weak that it could not, or could scarcely, be felt. When he died, that was easily explained. The aorta had not grown from his infancy, and the heart had enlarged ten times beyond its natural size. The same

effect occurs here from disease of the semilunar valves.

However, this man's mouth became very sore from the mercury, which had the effect of getting rid of the dropsy, and I think the heart beats with less violence. To-day I ordered him a slight diuretic, combined with a little tonic medicine.

DISEASE OF THE LIVER (WITH ABSCESS?)—There is the case of a person of the name of Mills, in York Ward, which has excited considerable interest. He had laboured under inflammation of the liver, and was attacked with pain just where the lungs and diaphragm meet; he had a short dry cough, with occasional shiverings and sweats; and I was induced to look upon it as inflammation of the liver, with suppuration. Since coming into the house he has lost the pain in his side entirely; he gets better sleep, and, by giving him small doses of magnesia, and sulphate of magnesia, his stomach and bowels have been restored to a healthy state, and his tongue looks a great deal better, but he still labours under a severe cough. To-day he has spit up a little puriform matter. Of course if there has been inflammation of the lower portion of the lung, in consequence of inflammation in the neighbourhood, there must have been some effusion of fluid into the substance of the lung, which would not get well without his spitting up a considerable quantity of mucus; but I still look upon the disease of the lung as altogether secondary; however, as the pulse was quick and rather sharp, I have ordered some blood to be taken, that we may see how far inflammatory action is or is not going on in this part, and, if necessary, to continue the bleeding, watching him. If there be disease of the liver with abscess, as I have supposed, it is of the posterior part of the liver, where you cannot get at it by puncture: but, on the whole, the man's general health is much improved.

COMMON CONTINUED FEVER, WITH ULCERATION OF THE SMALL INTESTINES.—Among the female patients there is scarcely any that I shall have occasion to speak of. There is a little girl on the left-hand side in Queen's Ward, whose case is of great interest, because it affords an instance of disease which at present exists to some extent,—which, indeed, is almost always falling under the care of the practitioner, and which has proceeded very well under the ordinary treatment. It is a case of common continued fever, which is always in this country, and which is an ulceration of the small intestine, to you of this case, you length, when it came in, the much delirium. Sometimes of the face was very hot, a

other was very cold. The abdomen was tender to the touch. The stools were very much like water in which cabbage had been boiled, leaving a deposit at the bottom of the vessel of a glistening appearance, something like metallic antimony. This was attended with very great inflammation of the bowels. The practice was to give her five grains of Dover's powder, and five grains of Hydrarg. cum creta, three times a day, and enough of beef tea to support her strength. Dr. Hore saw her and recommended a blister to the abdomen, which is very good treatment, and castor oil every other morning. Under this very simple treatment, the efficacy of which I can speak to in dozens of cases, the patient is entirely convalescent. But there is always fear of relapse in these cases.

Let us see what is the pathological state of the case. The glandular structure of the intestines, which is always pouring out fluid, partly to shield the bowels from obnoxious matter, and partly consisting of matter which is to be thrown out in the stools, is very extensively diseased. Of course, where it is very largely diseased, there is a constant thin and sanious discharge from the ulcerations. I am talking no romance to you. I have seen those cases of ulceration of the bowels over and over again.

Well, what is the method of cure? Of course you can do nothing in a hurry. You must induce a healthy action of the excoriated surface, and that is done by exhibiting alterative medicine, of a soothing and oily property, which helps to move the bowels at the same time. This is the *modus operandi* of the medicine, and the philosophy of the treatment. We owe a great deal of our knowledge upon this subject to the pertinacity of the French. They certainly overdid the subject, but we improved upon their treatment, and there is much credit due to them.

As the disease advances, however, this may happen. The ulcerations may be more extensive in one part than in another. They may now and then become very deep, and suddenly ulcerate through. I have seen more cases than one of that sort. There was a patient up-stairs, in whom symptoms of this sort came on. Violent sickness occurred on the preceding day; one of those ulcerations penetrated through the peritoneal coat, inflammation of the peritoneum came on, and the patient died, rapidly, from extensive inflammation. You have always to fear some accident of this sort. It is very rare; it may not happen in one case in a hundred, but it may happen. Another

The patient may be about, may be taking food, and then again. What is the result of this? Why that the inflammation of the bowels was in a progressive

state of healing, but the process of cure had not been carried far enough, when something obnoxious was taken into the stomach and bowels, and then the vital parts became more affected than they were in the first instance. There is more heat of skin, more sinking, and the patient is worse than ever. What you have to do in that case is, to endeavour, as far as you can, to cure the disease, and to support the strength at the same time. Here wine may be given, and even nourishing food, with great advantage. Sometimes if the bowels are exceedingly irritable, it is necessary for a time to give injections of starch and opium. Always give castor oil, moderated, as to the dose, according to the necessity of the case. You may give from a tablespoonful to half an ounce, or six drachms. Remember that in women, when they are the subjects of such disease, they are very greatly distressed, because the frame and nervous state of women are more easily excited than those of the other sex, and you must with them, probably, resort to mask and camphor. Some will perhaps say that this is an inflammatory disease, and that you are ordering stimulants. Well, but you are to keep in mind what you are to do. It may be true that you are for the time supporting a very serious injury to a part at a distance, but then you are not relaxing your efforts to cure the disease. I have dilated upon this more than perhaps I otherwise should have done, because at this time there are a great number of such cases, and I am quite sure, from my experience, that if they are treated as the case you have seen has been treated, nine out of ten will do perfectly well, even if you never see them again, should the same treatment be continued long enough. Still, you have always to fear a relapse,—sometimes a sudden fatal termination. I remember having seen two cases in which perforation of the bowels took place from ulceration, just at the time the patient seemed to be getting better. I have seen those ulcerations of an extent varying from the size of a pin's head to a size only a little less than that of the palm of my hand, with large raised edges and sloughs. Such cases, however, in later years, have been more rare; but in one year, when an epidemic prevailed, there must have been as many as twenty-three cases in this hospital, all of which were declared to be labouring under this disease. Latterly we have been very free from it.

I had some drawings, gentlemen, to show you, but the darkness of the evening will not admit of it; I shall, however, take care that at our next meeting we shall have lights, when you will be able to examine them.

There are several cases of "nervous disease," as it is called, now in the house.

There is that unhappy man Noland, who has universal palsy. There is a man in the bed opposite to him, the "sneezing man," as he is called, who labours under a very peculiar state of the nervous system. There is another man, in the same ward, of the name of Williamson, who does not appear to me to be quite right in his mind,—with paraplegia. I think these are the only three cases of importance. I am very fortunate in this respect at present, because in general I have a great number of those broken-down cases.

Now, then, there are two conditions in which you are to look upon the brain,—its functional and its structural conditions. You are to remember, as a general rule, that the functions of the brain may be disturbed to any extent, without any perceptible organic disease. But when there is permanent loss of sensation and motion in any of the limbs, and more especially if it be confined to a single limb, and is not the effect of rheumatic inflammation, it is a proof that there is organic affection of the brain; and dissection shows us, invariably, organic disease of the brain. If a patient is paralytic,—not a young woman, who does not know what the devil she would be at,—her case may be hysteria; but if the patient have paralysis, where there has been a fit, that case is one of organic disease of the brain. Ordinarily speaking, if there be paralysis of a limb and loss of sensation,—and it has come on very gradually, there is disease of the brain. In the great majority of instances, disease of the brain is first shown by some loss of power, or diminution of sensation, in some one or other of the limbs. If a lower limb is affected alone, it is called "paraplegia;" and I believe that the term employed is the same where there is an affection of a leg and an arm, as in the case of our "sneezing" man. If it be on one side only, it is called "hemiplegia." These are common expressions that are used in mentioning cases of paralysis. Now it is a most uncommon circumstance to meet with these diseases, without there being organic disease within the brain. In very old people, simple pressure of blood upon the brain will produce palsy. In those cases, and where the palsy has come on without a fit, it is very easily cured, which is a matter of great importance; but where there has been a fit, and the patient has been deprived of sensation and motion for a long time, and then recovers sensation or motion in any of his limbs, there is generally organic disease of the brain. When the patient has lost the use of his limbs, and that loss is attended with trembling—when he sees double, or when he sees only half an object,—there is great reason to suspect disease of the brain, and such cases are very dangerous; they are dangerous when you

would least suspect it. They may arise from slow disease of the brain, of the nature of scrofulous tubercles, or even what has been termed "softening" of the substance of the brain, which, as far as I know, in the adult, is a disease of the extreme arteries. All these are cases of organic disease of the brain.

When a patient has had what is called an "apoplectic fit," and he recovers with loss of sensation or motion of one limb, you are pretty sure that there has been on the opposite side of the brain an extravasation of blood. Though the extravasation has not been sufficient to destroy life, it has remained there; the red colouring matter which it contains has been absorbed, the mass of matter has been, as it were, drilled through with small holes, and remains there doing no harm. That I think is the most common cause of palsy; and the case is called "recovery from apoplexy," though the limb still remains impaired. Sometimes we have extraordinary instances of this. We had a very extraordinary case of it in the hospital the other day. A man tumbles out of a gig and gets a violent blow on the head, or a severe fall,—or, like a friend of ours in the hospital the other day, he gets a devilish good licking, and becomes paralyzed. There was a man twenty-five years of age, a prize-fighter, who got what is called "a belly-fall," or, as I should rather say, a "head-fall," for he came into this hospital perfectly paralyzed in all his limbs. He did not see double, nor did he see half an object; his mind was perfectly undisturbed, nor was any portion of the body more affected than the other. I looked upon this as a case of congestion of the brain, or such an injury as to cause a larger portion of fluid than natural to enter the brain,—not enough to destroy life, but sufficient to interfere with the proper functions of that organ. When he came under my care, I cupped him every six weeks from the back of the neck, took a small quantity of blood from him, gave him calomel, applied a blister to the spine, and dressed it with mercurial ointment, and in the space of little more than two months he was able to walk about. He then began to move his arms, and after a progressive state of improvement he went out by his own desire. I have no doubt that that treatment, if it had been kept up, would have entirely cured him; but I have no idea that his was a case of organic disease of the brain—it was a mere case of extravasation of blood.

Well, then, as to Holland who came in labouring under universal palsy, his arms and both legs were at first as nothing alive but his bowels. At that time the functions of the brain were disturbed. I took blood from him, as in the other case; put

and put a succession of blisters on the spine, which I dressed with mercurial ointment. He became a little better, and I then left off this treatment, which was pretty severe. He was, however, still a good deal affected, and upon a consultation with Dr. CHAMBERS, it was agreed that I should give him the tincture of cantharides, and he has, consequently, been taking thirty drops three times a day for two months. It has produced no strangury, and he makes more water now than it would appear he has ever done before. Whether that may have stimulated the sacral nerves I don't know, but I dare say it did, because by stimulating organs you sometimes stimulate the parts on which they are depending, or which depend upon them; but be that as it may, he has recovered the use of his arms, as you may see, and he is fast recovering the use of his legs also.

Now I look upon the two cases I have just mentioned, not as cases of organic disease of the brain, but as cases of effusion of fluid into that organ. I cannot believe that they are diseases of the brain itself, because, if they had been, I do not think I could have cured them.

There was a young gentleman about this house—a young physician—and his case will illustrate to you how these affections go on—who had headaches; his stomach was out of order, and he thought it was devilish odd that every now and then he saw double. He went to Mr. ALEXANDER, whom he consulted, and Mr. ALEXANDER said it arose from the state of his stomach. He next went to Dr. MAYO, and I think the Doctor had some sort of suspicion that it had something to do with some previous venereal attack. Then he went to another gentleman who recommended him to take steel. Then he was ordered to ride on horseback. Then some other gentleman called his affection “hysterical.” I don't know how venereal and hysterical affections agree together, but, however, we were all at a botanical lecture here one night, when the late Mr. BURNETT was with us; and we all went into the next room, and were very merry,—the young physician as merry as any of us,—but he was found dead in his bed next morning, from effusion in the brain. I believe there was no organic disease of the brain in his case, but only a disposition in the vessels to pour out blood. Why it is so I do not know, but palsy occurs from simple effusion of fluid into the brain, which fluid may itself be got rid of, and the tendency to which effusion may be got rid of also.

These diseases of the brain advances sometimes there is no palsy at all, but there is often death, but there is often recovery. These cases are very little short of the cases I have just mentioned. Such cases are very common, and you may see every twenty four hours in the patients in bed, forgetting

themselves. I remember having been called up two or three years ago to see a gentleman who had consulted Sir BENJAMIN BRODIE, and who had some pain in his head, and who told me that he sometimes forgot himself. I was very much fatigued at the time of my visit, but this circumstance of his forgetting himself weighed much upon my mind. He said he was going into the country, as he had been recommended to travel. I called next day, and said to his wife, “I should not advise your husband to travel. It strikes me, that this loss of thought, which he has mentioned to me, is more dangerous than you seem to think it. Take him out of London to a place where he can have just enough of company to amuse his mind, and keep him as quiet as possible.” She did so, and I saw him no more for above two years. I was afterwards called in to see him again, in consultation with Sir HENRY HALFORD, and he was then raving. He is now in a state of confinement. Now this is a case in which you see disease of the brain gradually creeping on.

Some years ago a gentleman consulted me about some obscure pains in the head, attended by some absence of thought. I suspected that organic disease was going on in the brain at the time, and I told his family so. He got a great deal better. He consulted me again three years afterwards for diarrhoea, just at a time when he was going to get married. I suppose he thought diarrhoea an inconvenient thing on such an occasion, for that was what he complained of, and of that I cured him. Two years afterwards I was sent for again, when I found him perfectly sensible, but looking very ill. He was sick occasionally, and complained of pains in the region of the liver. He had taken mercury and employed leeches. I saw him first with Dr. NEVISON, and next with Dr. CHAMBERS, but he was no better, notwithstanding all that had been tried. His father then said to me, “Do you remember an opinion you gave five or six years ago, that he had disease of the brain?” The circumstance recurred at once to my recollection, and I said that I did remember it. In about three months after that time my patient had paraplegia; he lost the use of his limbs and died, and no less than five serofulous tumours were found in the brain. This was a very remarkable circumstance, and the case altogether shows how long such affections may go on, without ending fatally or producing very characteristic symptoms. There was no affection of the mind in this case. The mind was clear and unaffected up to the last day of his life. Even the mind of the man whose head was beaten to a jelly by his antagonist, was clear and unaffected throughout. In the case of the young physician of this hospital, the mind was as collected as possible up to the

last moment. Reflect, then, on the one hand, how often it happens that the mind is disturbed without organic disease of the brain, and how often it happens that organic disease goes on without what you would take to be corresponding derangement of the functions of the mind.

With regard to the treatment in these cases, that must vary very much. As to the treatment of the patients who are now up-stairs, it has been very similar in all of them. There are various remedies for palsy, after the cause of the disease is at an end. In the first train of cases in which there have been fits, and the patient remains paralytic, local stimuli, and setons on the neck, a succession of blisters, and stimulating the parts with electricity and strychnia, are recommended. Such cases I find to be best treated by blistering the spine, and dressing the blistered surface with mercurial ointment. By that treatment I have seen a great many obstinate cases really recover; but it is one that it is difficult to pursue in private practice, because it is so very painful. I think also that cantharides is useful, and it strikes me that electricity might have often a good effect. With strychnia I can do no good. I have tried it in fifteen or sixteen cases, but I do not think I have ever derived the least advantage from its use. The most effectual remedy is the blistering, and the next is electricity. Another plan, particularly with aged persons, is that of taking away a small quantity of blood by cupping, six or eight ounces every fortnight or month, and keeping the bowels open.

Now, gentlemen, this brings me for the present to the conclusion of what I have to say to you of paraplegic cases, and the treatment of disease of the brain. There is really little to be done in them. However, I shall be able hereafter to illustrate my views farther, by a reference to other cases in the hospital as they occur. Our old gentleman I do not expect will get much better; but Noland, I think, will, as well as the man from whose head I have endeavoured to produce a discharge. He is now getting better, and that discharge is in effect the same as if a seton had been applied. You are thus keeping up a constant discharge by the use of mercury, effecting a considerable drain from the vessels that supply the head, and, probably, coming nearer to the seat of injury than you could approach with a seton. There is one thing to be observed with respect to the use of setons in hospital practice, and that is, that they are apt to be attended with erysipelas, and therefore I never order them. I am sorry to have brought you out such a night as this; but next time we may have a finer evening, and then we shall have lights, and perhaps more curious cases to bring under your notice.

LECTURE

INTRODUCTORY TO A COURSE ON

HYGIENE,

OR THE PRESERVATION OF

THE PUBLIC HEALTH,

BY

WILLIAM FARR, Esq.,

SURGEON, LONDON.

Delivered October 28th, 1835.

GENTLEMEN,—The subject of *Hygiene*, as far as I know, has not yet been treated in a course of lectures by any one in the metropolis; consequently the attempt which I am this evening about to make, presents more than the ordinary difficulties of a first lecture, and must plead for the exercise of more than an ordinary degree of indulgence. Instead of entering directly on the matter of the course, as should be done, were the general nature of the subjects to be discussed thoroughly comprehended, I shall after examining the history of Hygiene, endeavour to lay before you an outline of the whole course, and direct your attention to some illustrations which may enable you to appreciate, at their just value, a few of the points of view from which we are about to examine Human Life.

"Hygiene" is a naturalized French word, taken from the Greek *hygieia* or *hygia*, health. In its present form it is not, as Dr. Fournier has judiciously remarked in his "Bibliography," very agreeable to the English ear; and I should have adopted the term *Hygiology*, but from the dread of attempting two innovations. It is considered equivalent to *the art of preserving health*; and while the exercise of *Therapeutics* restores the sick to health, *Hygiene* is said to teach how life is preserved. Life is valuable,—“All that a man hath will he give for his life,”—and health is a blessing which sweetens every other joy, or bears men up even against misery; so when private individuals only are considered, health and the extension of existence should be the primary objects of Hygiene; to be attained at the expense of almost any sacrifice. Every member of the body may be lost, all its form and loveliness may have perished around it, the intellect itself may be gone, and man may remain,

“Sans teeth, sans eyes, sans taste, sans every thing,”

and yet may it be our duty to protract existence to its utmost span. Even a destitute individual, in a wretched condition, nothing but the intellect of every necessity, except the inevitable morbid heart, to survive which—to s

solemn duties, friends, country, or truth, for life, and so, *propter vitam perdere causas evitandi*,—hygiene itself offers no incentive.

Although the preservation of health and the prolongation of life are the great objects constantly to be kept in view in private hygiene, they are subordinate in public hygiene, where nations are considered to the higher end of developing the human faculties, and raising them to their greatest possible degree of organic perfection. Regarding mankind with a general eye, would an intelligent being desire to see a feeble, imbecile, effete population, vegetating through an antediluvian age of some eight hundred winters; or would he attempt to call forth all the energies of humanity, to flourish for a few years or generations, and then to ebb with terrible revulsion? Would he not rather seek to temper the intensity of life, so that, when multiplied by time, the greatest possible sum of vitality might be produced?

"Hael," the Saxon root of "Health," implies *strength*—hence we have "a hale man;"—and "Healer" was a bestower of Health. "Physician" and "Saviour" were translated by the Saxons "Healer." In speaking of the preservation of health, I wish health to be understood as implying not only that smooth course and equilibrium of the functions which is now commonly indicated by the word, or the state to which patients are restored after sickness,—but the *strength* and continued energy of the mental as well as the muscular system. "Cultivation" would be a more appropriate term than "preservation;" as the latter implies only *continuance*, while "hygiene" employs all external influences, and all our knowledge of the organs, the functions, and the habits of the human economy, not merely for its *preservation*, but for its *improvement*.

The true object of hygiene, then, is to increase the *sum of vitality* by extending individual life to its full term (averting death); by obviating sickness; and by increasing the energy of all the vital forces, whether nutritive, formative, locomotive, or sensitive and intellectual.

A history of life, of the natural and supernatural means which nations and legislators have employed for its preservation, the plans proposed by enthusiasts, and the valuable precepts which medical men and philosophers have successively deduced from the observation and experience of mankind, would afford us abundant instruction; as it would show the human mind at issue with a problem of the greatest importance, and the highest speculation.

My first step, however, will be directed to signalize the cultivators of hygiene; and to refer for more information on the subject than can be given in these lectures,—and to guard

against some false doctrines, which float like warning wrecks on the surface of its past history.

Egypt was considered by the ancients to be the seat and source of medicine. The observance of great bodily cleanliness, strict regimen, mild diet, from which the use of several animals was proscribed; vomiting, purging, and fasting, for three days successively every month; and a simple, invigorating education, inuring the youth to hardships,—these were some of the doctrines of the Egyptians, and formed part of their laws. Physicians were included in the learned class, constituting one all-powerful priesthood, to whom a third of the land was allotted. They practised their art for the advantage of poor and rich indiscriminately, their endowed riches raising them above the necessity of requiring fees. In the time of Herodotus, it is said, the plague was entirely unknown among the Egyptians, many of whom attained a great age.

The four last books of the Pentateuch unfold a great system of hygiene, not constituting a mere philosophic unapplied theory, but enforced by legal sanctions, and carried out in practice to the very letter of its enactments. Moses was learned in all the wisdom of the Egyptians, and adopted several of their practices; but together with the great idea of emancipating his countrymen, and carrying them from a land of bondage to a land overflowing with natural riches, came many profound principles of truth, resulting from the study of the moral and physiological condition of mankind, and a thorough knowledge of the external circumstances—of the country—the wilderness,—through which people were to be led. On account of the relation of miracles mingled with the narrative of Moses, some persons object to references being made to the Pentateuch; or to considering it as historical authority for scientific truths; but internal and circumstantial evidence proclaims its authenticity too strongly to justify the rejection of the facts which it contains, whatever differences of opinion may attend their interpretation. VOLTAIRE says that every thing about MOSES is supernatural: "Chaque peuple a ses prodiges, mais tout est prodige chez le peuple juif." After examining the records collected in the Pentateuch, the manners and the style of the Arabs, and all the other attendant circumstances, I think you will come, if not with WARBURTON, at least with MÜLLER and ROETTECK, to a different conclusion. I shall here assume that the facts are historical, and proceed to develop a faint outline of the Mosaic system of Hygiene; important, because it is the first recorded with detail, and because of the mighty principles it involves. The great theological system revealed by MOSES, I am neither qualified nor called upon to discuss;

in hygiene we have only to do with the physical facts.

MOSES, after carefully distinguishing the contagious diseases of the Israelites, commanded that the infected should be isolated.—In *Leprosy*—a cutaneous affection allied in character to Tubercular Elephantiasis—the suspected man was brought to the priest, who pronounced him “unclean;” or, if there were any doubts, shut him up for seven days, until the symptoms of the case became well marked. The “unclean” were put without the camp, and only visited by the priest: their clothing was burnt. When the people possessed settled habitations in Canaan, unhealthy houses were directed to be examined, and “scraped within and round about,” the dirt thus taken off being carried out of the city to an “unclean” place. The worst buildings were to be entirely broken down and removed.

In the disease of *Gonorrhœa*, the identity and antiquity of which, will, I think, appear indisputable to those who read the 15th chapter of Leviticus, every thing and every person touched by the patients, was declared “unclean”—to be set apart and purified by washing. Seven days of purification were prescribed for the cleansing of the impure person; who afterwards offered before the congregation “two turtle-doves or two young pigeons.” The minute regulations on this head deserve your attention; so do those relative to the menstruation of females, to their purification, and to cohabitation, particularly in the East, and among the Arabs. Circumcision, still practised among the same races, and, in some tribes, upon females, was intended to promote cleanliness; perhaps to prevent some diseases of the prepuce; or to obviate phymosis and paraphymosis. It was performed on the eighth day after birth; and often must have destroyed the most weakly children, who would bleed to death, or die convulsed: at least such a result has sometimes been observed among the German and Polish Jews. “A bloody husband,” said ZIPPORAH to MOSES, “art thou, because of the circumcision.”

Animals were allowed for food, but a great many species were prohibited. “Whatsoever,” says the Jewish law, “parteth the hoof, is cloven-footed, and cheweth the cud, ye may eat:” swine were excluded because they did not ruminate; coney and hares because their hoof was not divided. The prohibition of hares would recall to mind the modern Game Laws, were it not in conformity with a principle; and did we not know that Moses always carried out his principles to their most rigorous consequences. Birds of prey, “whatever in the waters hath neither scales nor fins, whatsoever goeth upon its paws,” and all flying creeping things, except locusts, grasshoppers, and beetles, were forbidden. The lat-

ter flying creeping things were, probably, not unacceptable in the wilderness. The ox, the sheep, the goat, the deer, and the chamois, were orthodox food; in fact, the classification excluded few animals which we now eat, except swine, hares, and rabbits. Everything that “dieth of itself” was pronounced inedible; and the blood of all animals was to be poured out.—“Ye shall eat the blood of no manner of flesh; for the life of all flesh is the blood thereof” *Lev xvii, 11*. Blood is rarely taken by Europeans, although it is drunk by some carnivorous animals and savages. It is not very palatable, but I am not aware that blood is indigestible. Some think that this enactment was intended to prevent cruelty; in support of which, BRUCE relates, that somewhere in Abyssinia, the fierce nomads drive their cattle and cut steaks from them as they are needed; but this very much resembles MIZELN’s story of the goose.*

The enactments relating to marriage, which are now adopted in Europe, were founded on the physiological law, that a degenerate offspring results from the intercourse of animals which are nearly related; and that a proper mixture of alien blood, can alone give birth to an untainted and vigorous race. Cons-ins and near relations, by being brought into contact when young, and when the affections are opening, too often lay the foundation of matrimonial alliances which infringe upon the general laws of Hygiene. What would have been the result of allowing the connubial union of nearer relatives? The denouncements of adultery, which was punished by death, and the strict investigation of virginity, disapproved promiscuous intercourse,—destructive of the bonds of families, calculated to yield a degenerate spurious issue, and likely to involve nations in exhausting pernicious diseases. Such a restraint was necessary, and justified by the truths of physiology, as, in the language of BEAUMARCHAIS, man is the only animal “qui boit quand il n’a pas soif; et qui fait l’amour en tout temps.”

The Levites (the priests or learned caste) were the medical advisers of the people: they were remunerated from the tithe, and received offerings on recovery. JENOVAH himself was his people’s physician; and on condition of their hygienic and religious obedience, declares, “I will take sickness away from the midst of thee; the number of

* Animal food is so abundant in some parts of South America, in Chdi, for instance, that it is not uncommon in that country to kill a large beast for the sake of the single meal of a few pounds, which a few travellers can make use of. The rest of its carcass, the remainder being too small to appease the hunger and desire of the natives, which are less delicate than ours, when flesh has been for some time exposed to the heat of a climate which is not very temperate. The statement of Bruce may have been correct.

thy days I will fulfil"—the great aims of our art.

Moses, assisted by the princes of each tribe and the High Priest, made two enumerations of the people, distinguishing "their families by the house of their fathers, with the number of their names, every male by their poll, from twenty years old and upwards, all that were able to go forth to war in Israel." The first census was made by assembling the congregation together on the first day of the second month, in the second year after they were come out of Egypt: 603,550 males above the age of twenty were enumerated. The force of each tribe is stated; the Levites, a month old and upwards, amounted to 22,000; the first-born of all Israel to 22,274. The males above twenty in western Europe constitute about a quarter of the total population, so that 600,000 males imply a total population of 2,400,000. Many believe that there is an error in this enumeration, but it is not necessary to examine the arguments on either side here; I only call your attention to it as the first census recorded, and to the fact that Moses employed this enumeration of the males of twenty years old and upwards, as a measure of the strength of the population at his disposal.

Before him were the thousands of Israel reluctantly torn from slavery, debased in intellect, and corrupted by circumstances, but now safe from Egyptian pursuit. Let us ask "what was the hygienic problem which Moses had to solve?" His great and avowed purpose was to put the Israelites in possession of Palestine, already fenced with walled cities, and guarded by a warlike population; the difficulties to be overcome were the traversing of an uncultivated but not extensive desert, obtaining supplies of food, and converting a race who were rendered dastardly and feeble by bondage into the warlike progenitors of an exterminating people, to extend its numbers from Lebanon to the Euphrates. Led to action in the first year, the unwarlike combatants, affrighted by the Egyptians, and easily turned aside by other small tribes, were driven back by the Amorites, like swarms of bees. Moses, from the moment of that defeat, devoted the entire generation to death in the "terrible wilderness," where pestilence, thirst, and hunger, in the course of forty years, destroyed all that bore arms (above twenty years of age), and only allowed the stronger children to grow up for the purposes of war, disciplined by the Mosaic laws. In the accomplishment of his purpose, the lawgiver spared no lives: at the hands of his own people were slain the conquered tribes were plundered, their riches were appropriated to the men only, who had not families, were spared to augment the number of children. Notwithstanding the

waste occasioned by death or war, on numbering the Israelites a second time, at the expiration of thirty-eight years, the great legislator records with dignified satisfaction, that the males of twenty years old and upwards still amounted to 601,730, animated by a very different spirit, and a far higher degree of vitality, than languished round the whitened bones which were sleeping in the desert. With the prophet called to curse them, gazing on one hand over the country they were about to possess, on the other over "Israel abiding in his tents;" his enraptured lips might well exclaim, "Who can count the dust of JACOB? How goodly are thy tents, O JACOB! and thy tabernacles, O Israel! As the valleys are they spread forth, as the cedar tree beside the waters. God brought him forth out of Egypt. He couched, he lay down as a lion, and as a great lion, who shall stir him up!" Thus Moses left the Israelites, a numerous nation, raised by great principles, a system of laws, and hygienic adaptations from slavery, and perfectly fitted to its great destiny; and thus he accomplished one of the most interesting physical regenerations recorded in early history. In contemplating this mighty work, shadowing forth preconceived ideas, and the result of theoretical principles, rigorously and sometimes cruelly enforced, the fugitive herdsman of Jethro, on the volcanic Sinai, standing before a rebellious people, and viewed with an enlightened philosophy, must remain for ever sublime in character, as he was conceived by ANGEO.

Turning now from Egypt and the southern shores of the Mediterranean, let us direct our attention, northwards, to the coast of Asia Minor and Greece, where the first temples were raised to ESCULAPUS and HYGEIA, and where human culture developed to a high degree all the physical and psychological powers of our nature.

The constitution of Sparta, founded on simple principles, and professing as its determined purpose, the development and equal distribution of physical strength and vitality among all the citizens, presents another remarkable example of the influence of hygienic agents on races of men. Some degree of uncertainty hangs over the early history of Lacedæmonia and that of its lawgiver LYCURGUS. We do not know in what precise hygienic condition he found and left that people; but it is almost certain, that after journeying several years, studying the laws of Minos, comparing the effects of Cretan simplicity with Ionian luxury, and making himself acquainted with the physical condition and the philosophic doctrines of the surrounding nations, LYCURGUS returned to Sparta, and established a new legislation, founded on education, which he looked upon "as the greatest and most glorious work of a lawgiver." The children were taught to endure labour, to fight, and to

conquer; they were lodged in the country; went barefooted, played naked or wore one upper garment, and slept together on rushes. They were fed on coarse spare diet, exposed to alternations of hunger and thirst, bodily suffering, and fatigue, and practised severe gymnastic exercises. After an animal is born, its character and nature are cast and fixed. So the education of LYCURGUS began before birth. He sought at its source and root to fashion the Spartan race in the iron mould of his system; for this purpose he first reduced, according to ARISTOTLE, the women to some rule: "he ordered the virgins to exercise themselves in running, wrestling, and throwing quoits and darts; that their bodies being strong and vigorous, the children afterwards produced from them might be the same. At certain festivals they sang and danced, unapparelled, but with all modesty, before the fathers, the young men, and all but the mocked and scorned bachelors of the city; and, to use the expression of PLATO, drew the young almost as necessarily by the attractions of love, as a geometrical conclusion follows from the premises. On marriage, the bride was carried off by violence; and only seen illicitly by the bridegroom, neither oppressed by wine, nor enervated by luxury (*Plutarch*). The father could not rear his own offspring before he had carried it to the elders; who, if the child was strong and well-proportioned, left it with the mother, and gave orders for its education by the state; but if it was weakly and deformed, commanded it to be thrown into a deep cavern near the mountain Taygetus. The women, too, washed their new-born babes with wine, to try, *PLUTARCH* correctly adds, "their habit of body; imagining that sickly and epileptic children would sink and die under the experiment, while the healthy would become more vigorous and hardy." The public education began at the age of seven years. For further details on the Spartan education, I must refer to *PLUTARCH*, *XENOPHON*, and *PATW*. These outlines present a picture sufficiently revolting to the better feeling of this age,—to us of the nineteenth century, who send foundlings to hospitals, nurse scrofulous infants, and educate the children, even of the labouring poor, in workhouses. Yet revolting as this system seems, it formed *LEONIDAS*, and the three hundred who fought and died at Thermopylæ "to obey the sacred laws of their country." It was founded on physiological laws, and realized at a great expense of suffering and life, the idea of *LYCURGUS*, in producing a chosen nation, endowed with extraordinary energy and an uncommon degree of vitality.

This investigation of the hygeinic legislation of the Hebrews and the Spartans, appears to me to preclude, to a certain extent, the necessity of further historic inquiry into

the hygeine of ancient and barbarous nations, for their institutions embody the practices not only of the early, but of the modern uncivilized nomad and fixed tribes which are scattered over the earth, and present them in a tangible, but improved and refined system. Hunger and necessity exposed the North American Indian to the hardships and dangers, the alternations of heat and cold, the inanition and fulness which the Spartan laws enjoined; the Indians were taught manual dexterity; their eye and senses were keen; they too could endure corporal suffering, and smile in the very pangs of death; they also disciplined their women, and abandoned their weak children. And so it was not only in North America, but in South America, and among all the vigorous races of savage men which we now call "barbarians."

In order to understand a system which attempted to augment the sum of a people's vitality, by eliminating and pruning remorselessly away all the weak shoots, imagine 1800 children born on the same day at Sparta. They are taken before the elders, and a certain number are rejected; those that are strong and well-proportioned are carefully educated, and their bodies are tempered by discipline to the circumstances in which they are destined to move; after the expiration of twelve years, only 1000 remain. Now conceive the same number 1800, born in a neighbouring city, where the circumstances are nearly the same, with the exception that all the weakly children are tenderly brought up, till they are driven by necessity from their parents' arms. How many of such children would be alive at the end of twelve years? Not all, but probably more than 1000; more lives would exist than at Sparta, but the vitality of many of these saved children would be feeble, their lifetime would be impaired by sickness, and afterwards, in youth and in manhood, they would be swept away by the implacable severities of a rude and uncivilized state, if these were not by some accident averted. If they lived to possess offspring, and that offspring extended to three or four tuberculous, scrofulous, enfeebled generations, their proportion would be augmented; while organic debility was weeded from the Lacedæmonians, the North-American Indians, and vigorous barbarians, in its germ, by the laws, and by the stern discipline of nature.

The Russians, in an extreme climate of rapidly alternating heat and cold, still bathe their young infants in the cold rivers, and then bring them suddenly to the warm stoves, to harden their constitution, according to Russian writers. I shall prove, by experiments, and the relative mortality of infants in the warm and in the cold, that extreme cold destroys the vitality of blooded animals; whereas, the cold-baths are a substitute for both the Spartan exam-

our Gallic neighbours in the use of their "Eau de Vie," in every case of recent injury. When, indeed, there is danger of a loss of vitality through gangrene, we may apply a firmentive cataplasm of yeast to the wound, and bathe the surrounding parts with the brandy aforesaid; but as this state of things is the inevitable consequence of previous and too violently increased action, running into mortification, the surgeon will use every gentle means that mercy can devise to prevent such a catastrophe, the best being found in proper agents to allay heat, which spirit or brandy would create and excite.

Page 382 of Sir Astley Cooper's "Treatise," contains his "general directions for the treatment of compound fractures of the fore-arm," which run thus:—"The arm should be supported upon a splint, so as to be kept perfectly free from motion." And I should for the same reason place the arm, the leg, or the thigh, upon a soft pillow. What! rest a sore limb on the narrow line of a splint board? Bid me repose on the bars of a gridiron! To think of keeping a limb "perfectly free from motion" there, is absurd. If you wish your patient *not* to be easy, *not* to enjoy repose, nor to keep his limb still, lay it on a splint. Again; "evaporating lotions should be applied;" but of what use can they be when the immovable bandage confines the hot vapours close around the limb? "And the limb should not be disturbed,"—true, but foreign aid creates more disturbance than the injury itself,—“unless the patient has symptoms of a suppurative process, when a small opening should be made in the bandage, to allow of the escape of pus, but still the bandages should be suffered to remain,”—that is, all must remain in *statu quo*; no one must examine the seat of injury. Like the man with the iron mask, every feature of the disease must be hidden from scrutiny, the masked party himself not daring to remove the dressings in which his limb is incased. "The bandages are suffered to remain." The patient treated in this way, finds that he has much to *suffer* besides the bandages. "The patient should be bled from the arm if the inflammation and constitutional irritation be considerable." "Certainly," said I, two years ago, after perusing the "Treatise," and transcribing the passage, in the excitement of the moment I added the following remarks:—"If it was, for some unknown reason, a *desideratum* to produce local and constitutional irritation, and to urge on that irritation to active inflammation, I know of no plan of treatment so likely to produce those mischievous effects as the above-recommended long-continued pressure on a pierced, lacerated, and fractured limb, where the natural sensibility is vastly increased by diseased action."

I now retrograde to page 173 in the

"Treatise," which relates to fractures of the lower portion of the thigh, *in the joint*. The treatment is thus described:—

"The limb is to be placed on a pillow in the straight position, and evaporating lotions and leeches are to be used, to subdue the swelling and inflammation. When this object has been effected, a roller is to be applied around the knee, and a piece of stiff pasteboard, about sixteen inches long, and sufficiently wide to extend entirely under the joint, and to pass on each side of it, so as to reach to the edges of the patella, is to be dipped in warm water, applied under the knee, and confined by a roller. When this is dry, it will have exactly adapted itself to the form of the joint, and this form it will afterwards retain, so as best to confine the bones. Splints of wood or of tin may be used on each side of the joint, but they are apt to cause uneasy pressure. In five weeks passive motion of the limb may be made, to prevent anchylosis."

In the first part of the quotation I only glean negative support for my pillow mode of curing fractures; but new light soon breaks in upon my plan,—original with me, because twenty years ago I confess at that time I had not read Pott, from the first day to the last of my attendance on a case of fracture, no other basis was employed on which to rest the limb, but a pillow and the bed, nor other restraint used than a bandaging nor other means than lotions, to accomplish a cure.

The case of Sir Astley is one of the worst of fractures, and as it is a most painful one, the limb is directed to be placed on a pillow, with a piece of pasteboard sixteen inches long and of goodly width, *interposed between it and the injured joint*,—a splint in a modified form! Venerable fathers of surgery, who have departed, just look over your shoulders, and see what a motley group ye have travelling behind ye! *Plaster-of-Paris dealers*, looking for orders to incase immovably straight a fractured limb; *carpenters*, with their boards and glue; *leather-makers*, with japanned splints; *ironmongers*, with tin splints; *blacksmiths*, with iron-plate splints; *Madons*, with cane splints (better be applied to some backs than broken legs); *sailors* from the Arctic seas, with Martin's whalebone splints; *milliners* with pasteboards, for Sir Astley's splints; and *breeches-makers*, in the rear, with straps and buckles to bind the broken ends of bones together. How many more I cannot stop to say, for really this system ought long since to have passed the rubicon of humour and railery, and journeyed into oblivion. Had the words "directed fractured limbs to be placed on pillows, without a splint" been the authority would long since have banished my puny efforts to banish the system needless. Had Sir Astley pulled

his patients, as I do mine, I should not now have been attempting to do my best to save future painful throes to those whose nerves are racked with pain in and out of hospitals under the torture of tight bandages and hard splints.

"But, perhaps," say some, "the splint is padded, and the pasteboard is wetted, therefore they are soft and yielding; what harm, then, can they do?" I ask, "What good can they do, which the simple pillow would not effect? Are you not thus striving to approach the pillow mode? You have relaxed a little, and softened down your treatment, in an *extremely painful case*; and if the pillow mode is the best in a desperate case of fracture, how much would it advance the cure in every common and less dangerous case?" Take this syllogism: The application of a pillow is right in the worst and most painful cases of fracture. Why? Because of the pain. But every fracture is painful; *ergo*, every fracture should have a pillow. But Sir Astley recommends stiff pasteboard, macerated in water until it become so much softened as to admit of its being moulded to the shape of the part. I grant that this is the least objectionable of the tribe of splints; but even this is unnecessary, and inflicts a memento of pain, which, even, is injurious. Soaked pasteboard, or light millboard, is only useful to envelop the arm or the leg of a person who must prematurely labour after a fracture. In this way my instructor, a talented surgeon (Dr. John Hughes) of Liverpool, was accustomed to use these materials nearly thirty years ago.

One paragraph respecting the more argumentative reasons why the splint is employed, and I quit reasonings for facts. A judicious writer (Mr. S. Cooper) says, "Hence there is a necessity of employing means for fixing the broken limb so effectually, that it may continue perfectly motionless during the whole time requisite for the union of the fracture." The truth of this I positively deny. It is *not* necessary that any limb, with any kind of fracture, should be kept so perfectly motionless. True is it that Sir Astley Cooper, at page 382 (before quoted), says, "The arm should be supported upon a splint, so as to be kept perfectly free from motion." These latter words are synonymous with "perfectly motionless." They echo the same sense. But in page 97 of the "Treatise," there is a discrepancy with some of the contents of page 382. In a note to that page, speaking of common fractures external to a joint, Sir Astley says the following important monition:—

"The object by saying, that at no time they speak of common fractures, and that of those which are compound. But no one would venture to say, that what is safe in a com-

time to time, that in proportion to that motion is the quantity of callus produced." Of course callus means ossific matter. The more motion, the more bone. Nothing can be plainer. So much for the theory of perfect immobility,—a theory founded on erroneous perceptions. Of course too much motion would produce great mischief, and as to the due quantum, "wisdom should be present to direct it."

Another argument used by the defenders of splints is this, that splints keep the extremities of the fractured ends of the bone in contact. Attend to Sir Astley Cooper's admission on this point; I quote *verbatim*, as in all the other instances:—"When a fracture occurs amidst muscles, those which are inserted into the fractured part of the bone, have generally a tendency to keep the extremities of the bones together, with some few exceptions." Why then use splints? The display is one of false science to effect what nature does by a natural process. If this in the generality of fractures be true, and what good surgeon will deny it? the arguments for splints are a waste of breath, and the simplest mode of cure should be at once admitted in their place.

I shall now aim to prove, that in no case of fracture whatever (that of the radius sometimes excepted), is anything more required than a strapped pillow, with its padding, a tailed bandage, and such lotions and dressings as it may be proper to apply to the surface of the limb. Simple fractures being by far the more numerous, are those with which we shall have most to do. The "exceptions" are fortunately few, and if they attended, as they too frequently are, by desperate and complicated circumstances! cannot be cured, they must, I suppose, be placed in the "chapter of accidents," in the usual way. My theory and practice shall be drawn from *bond-fide* cases,—not manufactured to support views that need the friendly aid of fictitious patients.

CASE 1.—Mr. Moses Crossman, sen., of the village of East Ogwell, in 1819 fractured his tibia by a fall from a horse, or, I rather think, by his horse falling with and upon him. It was a very bad simple fracture, attended with tumefaction and pain. One unfavourable and vexatious circumstance was (too common in country practice) the distance which I had to travel before I could get to the residence of the patient. Although there was much swelling in this case, yet an aluminous lotion and a tailed bandage, with the aid of a pillow and straps, cured this fracture in five weeks, when Mr. Crossman quitted his bed altogether for the day.

At this period, every case of fracture was a battle of words between the friends and

mon fracture must be inadmissible in a compound one. Fracture is fracture; and the nature of either case is the same.

myself, about the non-employment of the splints: in the present case, the Rev. Mr. W——— called in while I was engaged in the remedial operations on the leg. His stay was short. It developed a few questions on the "usual means" of curing fractures, accompanied by a look of contempt at my simple mode, and ended in a sneering sentence, muttered in the door-way, about "dabblers in the art." I only smiled, allowed the ill-bred gentleman to go his way unanswered, and resolved to persevere in my plan of curing fractures with as little pain as possible to the patient, who in this case was a healthy man of forty-five, who, as I have said, soon got well, and prided himself as much after the fracture on his small leg with a light low boot, and fine muscular calf, as he had done before it, and with as good cause.

CASE 2.—This occurred nearly seven years ago, and shall be related at greater length, because more witnesses can be cited to prove the truth of the details:—Mrs. Alsop, about seventy years of age, in the month of April 1829, was placed in great peril by the fall of a stack of chimneys during a storm, which dashed, with the roof under it, into her bed-room. I then resided in the adjoining house. Hearing an indefinite crash, I dressed, and hastened into the street, and soon found my way to the scene of danger. The bed was demolished, and the old lady lay under a great weight of bricks, slates, rafters, &c. On being removed from her alarming situation, the tibia of one leg, and the fibula of the other, were found to have suffered the injury of simple fracture. Mr. Charles Gaye, a surgeon of valued professional ability, whose friendship I have long had the happiness to possess, was also called in; as also was Mr. W. Y. Bond, another surgeon, who usually attended the family, the extent of injury done to the vital parts not having then been ascertained. But as I was first present, the more immediate care of the patient was willingly confided to me by Mr. John Alsop. We (the surgical trio) now formally deliberated on the case, and the best mode of securing the fractured limbs, when the following dialogue occurred.

Mr. Gaye. "Why, Radley? where are your splints?"

R. "I never use any; I have not used any for many years."

Mr. Gaye. "Where is your authority for that practice?"

R. "I have none but my own experience, that splints are useless in fractures."

Mr. Bond. "What! set a fractured bone without splints? I never heard of such a thing in my life!"

Mr. Gaye. "Nor I."

R. "Well, let me have my way on this occasion, and you shall have yours another time."

The concession was granted with a good-

natured smile of incredulity from Mr. Gaye, and a polite assent from Mr. Bond.

Mr. Gaye. "Proceed. We will look on."

Three lengths of tape, each of two yards, were each doubled, and laid on a common feather-bed, and on these straps a feather pillow, beaten smooth, was laid. Boyer would have exclaimed "C'est tout trop doux!" It is all too soft! Pardon me, say I, it is not too soft in any case. A sixteen- or eighteen-tailed bandage, I don't remember which, was laid on the pillow, and the patient carefully removed to the bed, and the most painful limb, that with the fractured tibia, was placed on the pillow. A reduction was then gradually and effectually made, the tails of the bandages were lapped over and over, and the sides of the pillow were brought to the sides of the leg, gently supporting it *in situ*, while the straps became a threefold means of keeping all steady. To support the foot, a piece of tape was sewn to each of the lower corners of the pillow, and tied close underneath the sole, which it supported much easier and better than does the usual "foot-board." My two friends assisted me, with many a humorous wink.

The leg was placed in the straight position, and rested on the calf and the heel. In order to relax the muscles to the half-bent state, or the degree of semiflexion, a large piece of flannel, perhaps a petticoat, is, in such cases, inserted between the pillow and the bed, for the purpose of raising and bending the knee-joint. The leg now presents the usual *declined* plane. The femur is a little thrown towards the pelvis, until the most important of the flexor and extensor muscles of the thigh and leg lie *en ease*. The under surface of the pillow was, in the present case, padded up, here and there, to support the small part of the leg, until the patient, after frequent and cautious inquiries on my part, declared that the limb seemed to lie with an equal pressure on every part. This latter circumstance is very necessary to be observed. Now look at the limb! As steadily supported as a ship resting in the stocks, and yet on so soft a basis, that nothing in it gives pain or uneasiness. What principle of surgery ought to have prevented this limb from lying in so much comparative ease, and the patient from reposing thus quietly? She did repose; and all persons in cases so treated, will repose likewise. All injuries will excite increased action, and produce some degree of heat, tension, and pain. The next morning my patient complained a little, and the surface of the tibia and the fibula of the other leg (treated much in the same way as its fellow) but in a different position, being placed on the bed, were moistened with the lotion above mentioned, much diluted. The skin having previously been sponged with tepid water, the wetted with the lotion above, were

and a hoop, fastened to the sides of the bedstead, supported the bed-clothes on the arch of its space, and prevented them from pressing on the toes or any part of the limb, and aided to keep it cool.

The tumefaction was moderate, as was the pain, because the heat was not allowed to remain confined long enough to produce its exciting effect; and as to other irritating causes, there were none, save that of the injury, the force of which had been very great, and at the end of a week caused great tenderness on the surface, the nervous papillæ being very irritable. *Tinct. Opii, Spir. Vini Rectificat.*, and *Tinct. Hyosciami*, were alternately used, with a pledget of lint, bathing the surface over and over again while any undue heat remained. Invaluable is this mode. The matter of heat readily unites with sulphuric ether, or a strong pure spirit, and flies off. The main point is not to reduce the natural heat of the limb much below, nor let it reach above the natural standard. On this hinge turns the state of suffering or of ease in these cases. Living so near to my patient, I was enabled to attend to this frequently. Indeed, she found the heat, pain, and soreness, thus fly off together so certainly, that I was summoned whenever there was a little return of pain. But the nurse was well able to attend to it, by turning off the tails of the bandage, wetting them, bathing the limb, and replacing the bandage as before. This was done perhaps twenty times in the day and night for a short period, and with the aid of a sedative and narcotic draught at night, and occasional doses of ol. ricini, she made good progress towards a cure. As for the incessant care with which I attended this case, and which, in narration, may seem tedious, to me it was not tiresome, though no one has a greater dislike of vicious irritability in the temper of a patient, excited as it sometimes is by factitious wants. But such a case as this (and there are many such) demanded every care. The patient was a feeble, aged woman, with all the querulousness of numerous years upon her, justifying and amply repaying the frequent treatment of adjusting the pillow by padding here or there under it, or the occasional insertion of a little cotton wadding between the pillow and the leg, for even a *soft pillow itself* will incommode a surface exquisitely tender. The limb was not moved, or only passively (and then moving pillow and all together), when the bandage was remoistened, and the fractured part exposed to view, by which nothing wrong could have been without being seen. But not once did the patient displace the ends of the bone. A small abscess occurred to effect such a union, and in the course of a long examination I never reflect to have attended to a patient who was so easily fretted by pain and pain.

At the end of the third week, my patient being naturally an attenuated subject, the eye could plainly distinguish, through the integuments, the breach of continuity in the bone, marked by a rough, irregular, thick line, or cleft, descending obliquely through the bone; appearing in a vertical direction, proceeding from the anterior to the posterior surface. But not the least deviation from a straight line in the general contour of the limb could be detected, nor could the finger discover anything in passing over its course, save the oblique line or depression described.

At the end of the fourth week, by comparing the legs, it was not distinguishable which tibia had been fractured, until the finger was slowly passed over the fractured part, and on the last day of four weeks from the accident, she walked across the room, leaning on the arm of her son. Now, remember, here had been simply a rolled bandage applied spirally around the leg. I said to her, "Madam, you have heard much of splints, and have been advised by some to have them, will you now wear one, or a piece of pasteboard?" Her reply was, "Neither, sir, I thank you; I feel very comfortable, and shall be able to take care of the leg myself." And from that time forward she did so, with no other assistant means than the spiral bandage, which was taken off every night and reapplied every morning. In the autumn of the same year, I frequently had the pleasure of seeing her walk in the street, with her accustomed light and nimble step.

Some have complained that little progress has been made in the treatment of fractures since the days of Hippocrates, but, I trust, that this is a great improvement.

CASE 3.—The next case I shall relate is one of a very different character from the last. It occurred in the person of a rough labourer, from the granite mountains of Dartmoor; presenting in many respects contrast enough to the preceding patient. The Hightor quarries, about nine miles from Newton, afforded employment to two or three hundred men, and as one of these was engaged on the granite bed, in removing what is technically called "the head" (a thick super-diluvial deposit of moor-stone, lying on the more compact rock), a mass of it fell, and buried him beneath. He was carried to a cottage at Hightor vale, from whence an express was sent off to me, for it was then a part of my occupation, and one irksome and laborious enough, to attend, on contract the sick and injured workmen at this place. I found him writhing under a fracture of the right femur, three inches above the patella,—quite near enough to the knee-joint. The man possessed robust strength and rigid muscular fibre. As to

the direction of the fracture, the great tension already existing prevented my knowing much about it at that time, but I afterwards found that it passed obliquely across the bone; the mass of stone having broken it short off. The man lay on a poor feather bed, with a coarse sacking bottom, laced up with a slack band, so he sunk down low enough posteriorly. What would Boyer have said on this occasion? "Soft and yielding indeed!"

In this state of things it would have been difficult to lay out the thigh straight, which I never do, according to Desault; so the method of lying "at ease," something in the way of our surpassing countryman Pott, was adopted; the lower part of the thigh and the whole knee and leg, being so supported on a long pillow, and padded up underneath, that a regular plane was obtained; no one part sinking lower than the rest. Slight extensions were made from time to time, in the hour or two employed to get it into a comfortable state, talking to and cheering him the while. The fracture being reduced, the bandage applied, and a hoop employed to support the bed-clothes, I left him.

Second day. The "gude wife" thought the hoop useless, and had taken it away. The thigh was rather too warm, and the man not by any means easy; so I nailed on the hoop to his old oaken bedstead, wetted the bandage, bathed the skin, and left him easy, in a better state, with full instructions to the mistress what to do to prevent pain.

Fourth day. Other cases prevented me riding over until early on the morning of this day, when I was summoned by one of those hasty messages that put an abrupt termination to all philosophic speculation, desiring me to come to him, for he had not slept during the night, from pain &c. I hastened up and found him with a red face and a bounding pulse, and the skin hot and feverish. How could this be? The hoop remained as I had left it, but on removing the coverings, cause enough presented. The careful wife, after wetting the bandage in the night, which she thought was too cold, had placed a heap of blanket under the hoop, upon the leg, instead of spreading it in a canopy over it. On removing it a cloud of hot gas arose, almost like the discharge on letting off the steam from a little engine. The causes of pain, restlessness, and fever, were at once fully explained to them, and in no very measured terms. The limb still lay well, and in a good position. Bathing the skin with tepid water first, and then with spirits of wine, caused evaporation until he said, "Cool enough now." He had a white tongue, so I gave him two large spoonfuls of the following julep, instead of abstracting blood, and left him:—

R. Antimon. Tartarizat. gr. ij; solve in Aqua Bulientis ℥i; et addo: Aqua Frigor. ad ℥iv; Liqueur. Annon. Acet. ℥i; Spirit. Camphora min. xx. • M. cibus, cap. cochl. maj. j om. bis hor. postea.

Some persons regard a little alteration of temperature as a trivial matter, but of all things in the treatment of fractures, this appears to me to be the most important in the inflammatory stage. Let the limb be placed and the fractured bones be reduced with whatever perfection of art may be used, if an atmosphere, *sui generis*, surrounds the limb, heat, tension, pain, spasm, and a starting in sleep, are sure to follow. In the present case no other mistake of the sort occurred. On the following day he was much better; he had perspired freely, and had from that derived what Mr. Pott recommends in strong terms; while it was to the patient an invaluable advantage, as Mr. Pott further says, "that the surgeon never found it necessary to have the leg or the thigh once, during the cure, removed from the pillow on which it had been deposited." Of course I feel the great practical value of this sentence, but Mr. Pott might, had not his splints been in the way, have said,—“The advantage of that mode of cure is invaluable which allows any old woman to open the bandage, permit the hot air to escape, and, after bathing the surface again, lay on the tails of the wetted bandage, and thus yield the patient ease twenty times in a day or night, with as much facility as she overlaps the belt of her gown,”—all which cannot be done where splints are used. Surgical dandyism in this case would have applied four splints,—one above, another underneath, and one on either side; and with so many “safeguards” few surgeons would consider it safe to tie and untie them every half hour. Besides, it would occupy too much of the time of a professional man; for surgical pride would not allow such frequent meddling with the established order of things by any old wife. Yet it would be impossible, even for a four-legged Chivon, to keep a patient easy at a distance of eight miles over the most hilly and rugged roads.

Perhaps some surgeons would have thought it right to bleed this patient as recommended by most authors, but I never yet bled a patient with a fractured bone (fracture of the rib and cranium excepted), nor shall I ever, while other antiphlogistics, Mindererus's spirit, and emetic tartar, are extant.

But to return. In ten days this man was safe from inflammation and its effects, and on the fifteenth day from the accident he was perfectly astonished to find himself

* *Mistura Camphora* would have been what is carried in the pocket should be parva.

under his foot and over his neck, pacing in front of his cot on a pair of crutches. I remonstrated with him on his danger, and represented to him the certainty of his having a crooked limb, but found all argument was uselessly opposed to his obstinacy, so I threatened to speak to Mr. Whittaker the superintendent of the mines. "He did not care a — for any body," he said, and would do as he liked. My first impulse was to forsake the patient at once, but mercy, as I thought, forbade, so on the next visit a pair of wide plasters of *emplast. lithargyriæ. resini* were overlapped on each other across the rectus femoris and above the fracture, which had barely united, at the same time admonishing the man to be careful. "When may I go a fishing?" however, was then, as it had frequently before been, his anxious inquiry. "Don't think of it yet," I always answered; but believe it or not who likes, at the end of three weeks (to a day) from the fracture of the bone, he went on one crutch, using his fishing-rod as a walking-stick, to a trout stream below Holwell Tor, and there fly-fished for the starvelings till he was tired, and almost every day in that fine season he was the next toward so employed. This was in the summer of 1825, and as he was off for employment on some other work, I lost sight of him until the last summer twelve months (1831); when, walking over one of the extensive marshy meadows of Kingsteignton, I saw him immersed up to the insertions of the glutei muscles in the muddy bottom of a water brook, sinking down at every step he advanced, with a sort of net in his hands, catching eels. Conversing with him about his thigh, he informed me that in one of his fishing rambles near Hightor, soon after he supposed the bone to be quite strong, he was lured so far from home by the romantic scenery about Becca Foll, that he became exhausted, fell on the ground, and might have died there, had not a boy, who was casually passing, procured a man and horse from a neighbouring farm, and he now laboured in most pathetic words to convince me how much pain he suffered on being set on the back of a wretched animal, whose false movements hurt him at every step as he passed over the rocky ground on his way home. Foolish fellow! His was the quickest, and, from his great imprudence, the worst cure of broken limb I ever had. True, the limb was always afterwards strong enough and long enough, but he turned out his foot awkwardly. Had he remained in bed for four weeks instead of two, it would not only have been well, but would have been well.

Figures like this, near the following candid motto in the "Surgical Dictionary," Mr. Samuel Cooper:—"In a fracture, near an articulation, it is to be

observed, also, that the splints have no command over the short fragment of a broken bone."

But is it that they should ever be laid over any portion of a limb at all. If some fractures will heal without the "command" of splints, why not more central fractures in the same bone?

Newton Abbott, Devon, Nov. 2, 1835.

. Another valuable paper by Mr. RADLEY, on this exceedingly important subject, is in our possession, and should our space admit of its introduction, it shall have a place in THE LANCET of next week. We consider that the facts which have already been advanced by Mr. RADLEY, are entitled to the particular attention of English practitioners, and we believe that the liberal and enterprising surgeons of the *North London Hospital* will be the first to give the plan of Mr. RADLEY a trial in the metropolis.

THE ACARUS SCABIEL.

In a clinical lecture delivered last week at the "London Infirmary for Diseases of the Skin," Dr. J. P. Litchfield, physician to the Infirmary, gave the following demonstration of the above supposed author of the irritation experienced in the itch:—

I have here, gentlemen, a patient, a young girl, from whom I shall endeavour to extract the *acarus scabiei*. She has been affected with the disease twice, although she is only ten years of age. She is the child of a tradesman, and caught the complaint of a female servant, who was immediately afterwards discharged. The child communicated the disease to her family, thereby fully establishing its contagious character. Frictions with sulphur ointment were employed to cure it, and the remedy succeeded after a month's assiduous application. Shortly after the patient was cured she came again in contact with the servant who had before infected her, and the result was a second attack of the disease; it is for this attack that she is now under my care.

You may perceive that the disease is at present confined to the fore-arm and hand; you will also observe that the eruptions are of different kinds, some being of the true primary vesicular character, others having the inflammatory and pustular appearance, which is caused, as I have explained, by external irritation. I now select three small vesicles which I surround with a circular ink-mark, in order that we may not confound them with the adjacent eruptions. By examining the interior of this circle with the powerful magnifying-glass which I here have, you will perceive, a small faintly-marked red line, diverging from the

centre pustules, at nearly right angles. This I consider to be a small furrow or canal, and if we are so fortunate in the present instance (and I succeeded yesterday and this morning in the same subject) as to find the acarus, it will be in this minute covered way. I now, therefore, take a needle about three inches long, with a fine flattened point, and puncture the pustule. I next gently and slightly slit up the integument in the direction indicated. If I mistake not I have now upon the point of my needle a small white globular body, scarcely perceptible to the naked eye. Having placed this shapeless point in the field of the glass, you will, on looking steadily at the object, see the globule, magnified to the size of the sketch which I now show you,* and which was made from an insect extracted yesterday. The insect under the glass exhibits so much vivacity in its movements, and such power in its many-jointed limbs, that you will have no difficulty in understanding the cause of the intolerable itching under which patients in this disease uniformly labour, and which we should find it hard to explain on any known pathological principle.

The acarus scabiei, as you are probably aware, belongs to the order *aptera*. It has, as you may perceive, eight legs, divided into flexible joints. The legs and proboscis are of a purple-red colour, as though injected with dark venous blood, but it is rather remarkable that the colour disappears almost entirely after the insect has been kept for some time. I have here one which was taken this morning from the same patient. For nearly an hour after its extraction this insect exhibited the same coloured appearance. But you will observe that the legs and head are now both nearly colourless. The body of the insect which I have last shown, is dry and shrivelled, very different from the full form and gelatinous appearance of the recently-extracted insect. In both cases numerous small spinulae or hairs may be seen passing off from the extremities and body of the animal.

LIGATURE OF THE SUPERIOR THYROID ARTERIES,

IN CASES OF

LYMPHATIC GOITRE.

REPEATED success has confirmed Professor CHELUS, of Heidelberg, in the favourable opinion which he has held for several years, on the propriety of tying the superior thyroidean arteries in cases of large

goitre, contrary to the advice of many surgeons. In all cases of *lymphatic* goitre, where these arteries are much dilated and sensible to the touch, this ligature is as much indicated as in the *vascular* goitre. In four cases, where M. Chelius has tied these arteries, the success of the operation was not retarded by any accident; the two following will serve to show what benefit we may hope to obtain from the process, even under the most unfavourable circumstances.

CASE 1.—G. Haltenstein, twenty-six years of age, was attacked at the age of fourteen years with a tumefaction of the thyroid gland, which gradually increased. At the age of sixteen, in consequence of the patient having carried a heavy load on the head, the tumour became much larger, and during the last two years remained stationary. The goitre now presented a nearly uniform tumefaction; however, the left lobe ascended somewhat higher than the right; the tumour also exhibited a central, and two lateral portions, divided by two furrows, very sensible to the touch. The tension is equal throughout; the skin not altered, merely covered by blue varicose veins. The tumour extends from the os hyoides to a little below the upper part of the sternum; its dimensions before the operation were as follows:—

The greatest circumference at the base of the tumour, 25 inches, 4 lines.

Distance from one angle of the lower jaw to the other, measuring over the tumour, 18 inches, 6 lines.

Transverse measurement at the most voluminous part, 15 inches.

Perpendicular measurement from the os hyoides to the sternum, 7 inches, 10 lines.

The left thyroid artery was felt beating for the extent of about an inch at the left upper angle, but the vessel was not enlarged. On the right side the pulsations were more sensible, though more feeble.

The inconveniences occasioned by the pressure of the goitre were very great; the patient slept but little; he swallowed with difficulty; the respiration was short and difficult, and on the least effort he was attacked with pain in the head and oppression about the chest.

The ligature of the left superior thyroid artery was performed on the 23rd of March, 1834. Its tract being determined by the pulsations, an incision was made in the direction of the vessel, which was isolated with difficulty from the tissue of the goitre. The wound was immediately closed with sticking-plaster, and the patient bled. Rest and a strict regimen were ordered. In the evening the patient felt well enough; the tumour was flattened on the left side, and was

* An inch and a half in its long diameter, and very similar to the engraving which we gave of the animal in THE LANCET for Oct. 4, 1834, page 61.—Ed. L.

insensible. The wound healed rapidly, and on the fourth day after the operation the tumour was reduced to the following dimensions:—

Circumference of the base diminished by 5 inches, 5 lines.

Transverse measurement, diminished by 2 inches, 6 lines.

Percpendicular measurement, diminished by 3 inches.

The inconveniences to which the patient had been subjected now gradually disappeared, and he was soon able to return to his ordinary occupations. The tumour continued to decline. Towards the end of 1834 the left side had become remarkably smaller than the right, and the patient enjoyed the full exercise of all his functions; he was advised to submit to a new operation in case the right side of the tumour should increase and give rise to any inconvenience; but as yet this has not happened.

CASE 2.—N. K., 30 years of age, of a weak and scrofulous constitution, perceived the first trace of goitre at the age of 11. The disease was hereditary in his family, his mother and five of her brothers and sisters being also affected. The tumour having gradually increased, and occasioned uneasiness in respiration, the patient, who had previously tried various internal remedies in vain, presented himself for treatment in June 1832. The tumour, as large as the doubled fist, corresponded to the left lobe of the thyroid gland; it had a pear-shape, and the inferior rounded part hung down upon the upper third of the sternum. The tumour was hard and uneven, and exhibited in several points traces of the application of the seton. The superior thyroid artery, very much dilated, was felt pulsating strongly, over a great extent of surface. In this case the knotty form of the tumour, its long duration, and the change of texture produced by frequent applications of the seton, left little hope that ligature of the artery would be attended with success; the case was one which rather seemed to require extirpation of the gland; however, the ligature was chosen as a means of rendering at least any secondary operation more easy. The two superior thyroid arteries were therefore tied; the wound healed readily by the first intention. The tumour immediately became more flaccid and soft, and gradually diminished in a manner beyond all expectation. After having remained a considerable time in the hospital, during which the swelling still decreased, but not very sensibly, the patient was discharged, with injunctions to return again in case of necessity.

The disease is followed, according to

Professor CHELIUS, for the ligature of the superior thyroid arteries, should vary according to the circumstances of the case &c. As it is impossible to determine beforehand in what direction the first incision should be made, the Professor considers the rules laid down by JAMESON, ZANG, WALTHER, LANGENBECH, and others, as illusory. He thinks that the vessels never pursue a constant direction, and are, moreover, frequently displaced by the tumour. The only guide we can follow is the pulsation of the artery. We are sometimes compelled to take it up above, and sometimes below the omo-hyoideus muscle, but in either case this is done with equal facility.

CASE OF

CROUP WITHOUT COUGH.

The following case, observed by Dr. Michaelis, is so interesting, that we are induced to extract it, nearly entire, from the second number of *Hufeland and Ossen's Journal* for the present year:—

CASE.—In the month of February 1831, the author was called on to see a child who had been dangerously ill for several hours. The patient, between four and five years of age, had been quite well the day before, and was suddenly taken ill within a few hours of the visit; when first seen he was lying on his back in bed, and the face was expressive of great anxiety and suffering. On examination, nothing could be discovered but some trouble in the respiration. There is no pain in the abdomen or head. The disease was therefore regarded as a severe inflammation of the lungs, and some leeches were applied to the chest, and ammonia and tartar emetic were given in small doses. At five o'clock p.m., the child's state was much worse; the difficulty of respiration is so great as to cause apprehension of instant death; the child lay immovable on its back, the head was thrown backwards, and the arms stretched out on the bed so as to form a right angle with the rest of the body. The little patient *had not yet coughed*, and, indeed, it was doubtful whether he was hoarse before, as the parents are not certain on this point.

The absence of any cough in the present instance was calculated to throw great difficulty in the way of diagnosis, and after having reflected at the bed-side on the various affections of the respiratory apparatus to which children are subject, M. MICHAELIS was induced to ask himself, "Could this be

an example of croup without cough?" Every effort was made, but in vain, to force the child to cough, until at length the object was obtained by forcing him to respire the vapour of strong vinegar; this produced the wished-for aspect; a violent cough, having all the characters of the croupal cough, came on. The true nature of the disease was now manifest. A vomitive was immediately ordered, and the child threw up a quantity of glairy mucus, and a substance whose membranous nature was quite evident. The repeated vomiting was followed by a marked improvement in the respiration, and the little patient lay with his arms more close to his body. Leeches were now applied to the neck, and calomel, with sulphur, antimonii, was administered, to procure copious stools. On the following morning the child appeared much better, he slept pretty well, and the cough was softer and more easy. Towards morning a general sweat had come on; the respiration was much more free, and without any peculiar tone. The calomel powder was continued, with the antimony, and, finally, senega was given, and in four or five days the child was so completely recovered as to be able to play about with his companions.

M. MICHAELIS justly considers this case as unique in the records of medicine; because the cough, which all writers mention as the pathognomonic symptom of the disease, was here artificially excited, while in the cases given by HEIM, the true nature of the disease was not discovered until after the patient's death. In his excellent treatise on croup, HEIM makes the following remarks:—"Even the best physician may mistake the nature of this disease. Not long ago a child two years of age died at Berlin, who had been hoarse before he was attacked with the disease, and therefore did not present the change from a clear to the croupal voice. It was only two days before his death that I discovered the true nature of the complaint, and that principally from the circumstance of his having the head constantly thrown back; all aid was now too late to save the infant's life." And in page 15 he says:—"We sometimes observe catarrhs without any hoarseness, and the latter symptom is frequently but slightly marked in several cases of croup, but when it is very much developed, the patient is incapable of producing the characteristic tone." Finally, at page 19, he says:—"When the voice is totally extinct, the physician may readily be deceived; I confess that I have been mistaken this way more

than once." These citations prove, beyond all doubt, the existence of croup without its peculiar cough, and it seems strange that the circumstance should not have drawn the attention of writers on diseases of children, to whom HEIM's work cannot be unknown.

In the first case of croup which we published in the first number of the volumes of THE LANCET for the present year, page 29, the child's voice was completely extinct, and the efforts of cough took place without any of that crowing sound which is peculiar to croup. The absence of these two symptoms is noted in the report of the case, but as no doubt whatever existed as to the nature of the disease, sufficient attention was not paid to a circumstance which, in other cases, would certainly have rendered the diagnosis very difficult if not impossible.

EXISTENCE OF SUGAR

IN THE

BLOOD OF DIABETIC PATIENTS.

A PAPER on this subject has been published in one of the continental journals, by M. AMBROSONI, head apothecary to the hospital of Pavia. Chemical research has already placed beyond doubt the existence of saccharine matter in the urine of persons affected with diabetes mellitus, but the presence of sugar in the blood or other fluids has as yet remained very doubtful. Marcet, Wollaston, Prout, Kane, and, lastly, Berzelius, have endeavoured to discover it, but without success. Wollaston was so frequently disappointed, in his attempts at discovering saccharine matter in the blood of individuals labouring under this affection, that he was led to conclude, either that the sugar is formed in the kidneys, or, being produced in the stomach by an imperfect digestion, is carried at once to the bladder by some unknown passage. The pharmacien of the Pavia hospital has been more successful in his experiments. In the month of June 1834, Professor Corneliani forwarded to him about a pound of blood drawn from the arm of a patient whose urine had furnished a large quantity of sugar. The following process was employed for its separation. The clot and serum, mixed with a certain quantity of water, were gently heated, the liquid parts separated from the solid, and filtered by a filter. The residue was a dull-red colour. In order to ascertain the colouring and other animal matter

treated with the subacetate of lead, which threw down a dense, dirty-white, precipitate. A current of hydro-sulphuric acid was now passed through the mixture, to throw down the lead; the residue gave a pulsatious, dark mass, which, when diluted with water and filtered, became a brown liquid; this latter was boiled in an aqueous solution of white of egg, which, by coagulating, divided the liquid into two parts, one flocculent, brown, and insoluble, the other liquid and colourless. The latter, being gently evaporated, gave a sirup analogous to the same which had been extracted from the patient's urine. The sirup, being laid on one side for a few weeks, gave rise to the formation of colourless crystals of a prismatic form, and with a rhomboidal base, in a word, exactly similar to those of sugarcandy. The non-crystallized sirup having been exposed to a temperature of 26°, R. with a little beer-washings, the vinous fermentation was soon developed. The quantity of sirup obtained from the pound of blood might have amounted to about one ounce; the crystals of sugar weighed nine grains.

The same chemist has also analysed the blood of a female who died of diabetes mellitus, but he was unable to find the least trace of sugar, either in the blood itself, or in the serum effused into the cavity of the pleura.

VENEREAL DISEASES OF THE TESTICLE.

Abstract of a Communication by J. W. Cusack, M.D., of Stevens's Hospital, Dublin.

So many surgeons of the highest authority have admitted the existence of venereal affections of the testicle, that we must assume the existence of an acute or chronic enlargement of the testis, originating in the action of the venereal poison, to be proved; but here our knowledge, derived from published opinions, ceases. These affections have never been classed, described, or explained, according to their differences, from dissection. From the general conviction of the profession, Mr. Cusack considers himself justified in assuming the existence of a disease of the testis depending on the presence of the venereal poison in the system; at the same time he admits, that as the disease occurs in the more advanced stages of constitutional lues, and after the use of mercury, it must be entertained as to the disease, which constitution and treatment are progressing this disorganization, so far as he has observed, in the body of the testis, and

there is at first little alteration in the form of the organ; as the enlargement advances, the tumour becomes more globular, the epididymis soon being lost in the general mass; the tumour has a fleshy feel, but differs much in density in different parts. Partial adhesions in the cavity of the tunica vaginalis, combined with effusions into that cavity, even independent of the internal changes which may be going on, render primary smoothness and uniformity of the surface an uncertain symptom; so uncertain indeed and so little uniform are the primary appearances, that Mr. Cusack believes that the best practitioners would be unable to make a perfect diagnosis of the disease, if unacquainted with the history of the case, and the attending circumstances. Its termination is either resolution or suppuration or induration, and the formation of granular bodies, ending in total destruction of the functions of the organ. Mr. Cusack hesitates to believe, and is unable to affirm from his own practice, that this affection of the testis is met with in the earlier stages of secondary symptoms, or during the presence of any of the forms of true papular eruption. The acute form accompanies venereal hectic, pains in the bones, and either a scaly eruption or perhaps a solitary spot, apparently belonging rather to the genus acne; but these instances are comparatively rare, and of fifty patients at present under treatment in Stevens's Hospital, there is not one case to adduce in confirmation of such an opinion. The patients who suffer from this affection are those persons who labour under affections of the periosteum and bones, and bear the marks of having suffered from pustular and tubercular eruptions. Specimens of the disease were submitted to the Surgical Society, and these were wholly derived from persons whose constitutions were broken down from the protracted forms of the disease with which practitioners are familiar, but neither from his own opportunities nor from any other source could Mr. Cusack exhibit a specimen of the changes which take place in the more curable forms of secondary syphilis. Ten preparations were laid on the table, exhibiting the disease in all the stages of its progress, from a small circumscribed tubercle, in an otherwise sound testis, to the contracted, indurated, and completely disorganized gland. The structure of the tubercle is rather soft, but harder than common scrofulous tumour, and surrounded by a thickened layer resembling a cyst, the product of inflammatory action. In one preparation the tubercle was in the lower part of the testis, which was otherwise so sound that the epididymis admitted of injection by mercury, while in the opposite testis the tubercle was softened, and contained a glairy fluid.—*Dub. Journ.*, Nov. 1835.

OPERATIONS FOR STONE.

The following statistique of operations performed at the *Hospital of Incurables* and of *St. Mary*, at Naples, during the Spring of 1835, we extract from the *Gaz. Med. de Paris*, No. 41:—

The neck of the bladder was divided downwards and to one side. Professor Dr. RENZI is in the habit of publishing annually the statistics of all the operations for stone which are publicly performed at Naples. How much would be gained by science if the surgeons of our great hospitals were compelled to imitate this example, for the principal operations which they are called upon to perform! We should then have a body of authentic facts upon which confidence might be placed, and from which deductions of the highest value might be drawn.

At the *Hospital of Incurables*, ten operations were performed; six of the patients were below ten years of age, the others had not reached that of puberty. In four cases the stone was large; in three it was small; in three of a moderate size. There were nine males and one female. Only one patient died of the ten; after having cut into the bladder, the surgeon was unable to extract the stone. The bladder, after death, was found much inflamed, almost gangrenous, and the mucous membrane was reduced to a kind of pulp.

At the *Hospital of St. Mary*, four patients were cut, and all recovered: three were below fifteen years of age.

Since the year 1821, up to the present time, 454 patients have been operated upon in these two hospitals. 439 males, 15 females; or 216 children, 191 adults, and 47 old. Of these there were cured 388; died 66; giving an average of one death in nearly every seven cases.

ARTIFICIAL ANUS CURED BY A NEW PROCESS.

In the month of September last, M. AMUSSAT, of Paris, was called on to see a child two days old, who had not yet passed any meconium. The anus existed, and was well formed, but the rectum terminated by an opening in the vagina. On examination it was found that the rectum did not exist for two inches from the anus. M. AMUSSAT, therefore, determined on seeking the extremity of the great intestine, separating it from its attachment, and fixing it by suture to the opening in the skin; for this purpose he made a T incision between the vaginal

opening and the anus, and having introduced the finger by this opening, he separated the vagina from the coccyx and sacrum, until he arrived at the blind end of the great intestine, which was placed above, to the right side of the sacro-vertebral angle. Arrived at this point, the manœuvres produced a desire to evacuate the meconium. The gut was recognised by Messrs. Denenx and Lebaudy, who were in attendance. It was seized with a hook, separated from the surrounding parts by the finger, and drawn gently down to the opening in the skin, where it was fixed with several points of suture. It is now twenty-eight days (said M. AMUSSAT at a late meeting of the *Academy of Medicine* since the operation just described has been performed, and no accident has occurred, the child being in the most satisfactory state.

INQUEST AT FARNHAM.

To the Editor of THE LANCET.

SIR,—The details of the subjoined case will go farther to prove the necessity for the appointment of medical coroners, than any which I have yet known to be brought before the public. The verdict delivered was "Accidental Poisoning," and nux vomica was the poison sworn to have caused the fatal result. The medical evidence and a general outline of the inquest I transmit for publication, well assured that the pages of THE LANCET will be open to the insertion of facts of so much general importance, especially as the character of a respectable individual is involved in the inquiry, the medical evidence having guided the coroner and jury in the delivery of the charge and the verdict. No other channel offers to clear the person on whom odium is attempted to be cast (the local opportunity being hermetically sealed), and he here, therefore, begs to challenge those opinions which can decide the question at issue. The details are given from memory, for on applying to the coroner for a copy of the depositions, he declined granting one, on the ground of the concession being illegal, though he politely read the depositions to me; and as Mr. Portello appealed to me in his distress, I am bound to carry the inquiry forward to an issue, that I may not be involved by undertaking a defence.

On Thursday, the 8th of October, a travelling man and woman, who were the property of Mr. Postello, a druggist, were requested some medical assistance. The child, thirteen months old. The child and its bowels were much confined.

viate which latter symptom, he gave two aperient powders. (In the course of Mr. Postello's examination he stated his entire forgetfulness of this circumstance; but that the man and woman had applied to him was distinctly proved in the evidence). The first powder was given on the Friday morning, and was followed by sickness, the stomach doubtless rejecting it from previous disorder; nothing having passed the bowels, and the child becoming more drowsy and insensible on the Sunday morning, the other powder was given. Its effects were four stools, and no sickness. Nothing further was attempted for its relief until Thursday, when Mr. Bury, a surgeon of the town, was called in. He found the child in a state of coma, with very contracted pupils, and at first slight pronounced the child to be *poisoned*. He attended it up to Friday, and as the coroner also declared to me, administered medicine, although it was not stated in evidence that he did so. On the Friday it died.

The rumour of a case of poisoning justified the holding of an inquest, Mr. Bury having previously opened the body and head to illustrate and establish the fact. A copy of the exact words of the evidence having been refused, I can only state the substance; and as the material part is the post-mortem examination, I give it as read to me, waiving the phraseology.

Mr. Bury stated that he found the brain healthy, but with rather an *undue quantity of water in the ventricles*. His researches were then transferred to the body, where he found the lungs and heart and the abdominal viscera healthy, excepting the stomach, in which he found a powder, which he secured by a process which he specified, and instantly adjudged it to be nux vomica. He stated that as no analytic test could establish its identity, he depended on analogy; and having procured some of the recent drug, he mixed it with the fluid of the stomach, tasted the suspected and the real, and was satisfied that nux vomica had killed the child. It did not appear in evidence which of the two he had tasted first, nor how long a period there was between tasting the true article, and the supposititious one. Having thus satisfied himself as to the nature of the poison, he stated that there were traces of inflammation of the coats of the stomach. This closed the substance of his medical evidence.

It appears that Mr. Postello had forgotten every thing connected with the dispensing of the medicines; but the local situation in his shop of a jalap preparation which he used for purgative purposes, and the powdered nux vomica were remote from each other, and it was shown to be the fact on cross-examination. In the routine of a business, it is possible that no remuneration may be paid to personal attendants, and Mr. Postello failed to remem-

ber the individuals who had called on him about the child. The verdict was returned, and Mr. P., not by direct charge, but by *in-fuendo*, was asserted to have caused the death of the child, and this too even by one of the jurymen. On the Sunday following, he sent for me, and begged me to inquire into the justice of the allegations. I saw the parents of the child, and then for the first time it was discovered, that Mr. Bury had himself given it medicines; and from the woman I learnt, as well as from the father, that the effect of Mr. Postello's powder was precisely that which was intended. Mr. P. having entrusted his case to me, and well knowing the serious consequences of such a general impression, I advised him by all means to adopt the most strenuous measures to clear himself from so unhappy a suspicion. We went to the coroner, who feelingly expressed his sincere regret, and viewed the case in the most serious light, promising Mr. Postello to give him, if possible, a copy of the evidence; but this has since been refused on the ground I have named. The question of the propriety of a druggist prescribing for a sick person is not for me to determine. The proceeding had already taken place, and my desire is to establish the impossibility of the powder given by Mr. Postello having poisoned the child. I believe that no reasonable man, certainly no medical man, will assent to the allegation, that a medicine given for a specific object, and fulfilling its design, and taken on a Sunday morning, could be found in the dead child's stomach on the Friday morning. As to the accuracy of the mode of determining the poison adopted by Mr. Bury, or its incompatibility with the appearances found in the stomach, together with the state of health which the child was admitted to have possessed for the nine days previous to the fatal event, I have nothing to say. I appeal to every reflecting mind to decide whether the powder so found, could be the powder given by Mr. Postello. Both the father and mother declared, that the child became sick, very sick, from the medicine given by Mr. Bury, and that it was much convulsed after taking it. Now the ways of Providence are indeed mysterious, for the elucidation of crime and criminal carelessness. Mr. Postello's medicine, after operating four times, six days before, must, to have so poisoned the child as Mr. Bury imagined, have traversed back, as a purgative, many feet of bowels, to reach the dead child's stomach, and then maintained its position in defiance of the vomiting produced by Mr. Bury's medicine. It shall be conceded that nux vomica was found; found by Mr. Bury. All I seek to prove is, that Mr. Postello was not the instrument of its introduction there, either directly or indirectly. But why do I argue for a conclusion that must be inevitable? This inferential mode of destroying

a character, is sad indeed. Had Mr. Postello been provided with a competent medical friend at the inquest, the coroner and jury, if they had believed the child to be poisoned, would never have suspected Mr. Postello of the act, and that the coroner had that impression on the inquest I can positively assert. A hundred times better would it have been for Mr. Postello to have been committed for the crime of poisoning at once; he might then have cleared himself on his trial, in the minds of his townsmen, from what has excited, and is calculated now to continue to excite, distrust. But this inquest is final, and although to clear Mr. Postello every fair proposition has been made, especially that of strict inquiry by a select body of medical men, the appeal has been contemptuously rejected, and a threat of action even hinted at, if he perseveres in the demand. The coroner, Mr. Woods, is in every sense a gentleman, and was most anxious that the character of Mr. Postello should be cleared; but the only resource now is the public press; and to your journal he appeals, as to the most honest of medical periodicals. With respect to my position in the affair, Mr. Postello having thrown himself in the emergency on me, I cannot allow the facts to be smothered.

That medical knowledge in a coroner is a most essential requisite for the good both of the public and of individuals, must be too obvious from the history of this case, to need further exposition from me. I remain, Sir, your most obedient servant,

G. V. ROGERS, Surg.

Farnham, Surrey, Oct. 26th, 1835.

P.S. The mother was found by Mr. Bury in a state of extreme intoxication, when he first visited the child.

THE LANCET.

London, Saturday, November 14, 1835.

A FACT which is most happily characteristic of the hole-and-corner proceedings in the College of Surgeons, has just been presented to the profession in the election of a new member into the Council. We ought, in truth, to make some distinction between the two last elections, referring specifically to the first of them as furnishing the best evidence of the event to which we allude. Mr. GREEN, of *St. Thomas's Hospital*, was not chosen the other day by the self-perpetuating junta, but was, positively, elected

some months since, on the resignation of Mr. LYNN; and yet so secretly, so covertly, and—we may, in justice, state, with reference to the great body of the members—so clandestinely, that it was not known up to this very week, to the profession in the metropolis, that Mr. GREEN had become a member of the Council; and, in reality, the circumstance is now for the first time published to the profession generally.

What a state of things is this! And yet this system of secrecy has been endured by the medical community since the barber-surgeons were first erected into a corporation! Even the charter of 1800, under the authority of which these odious secret elections were conducted, was merely, in spirit and in letter, an emanation from the Act of the 18th of GEORGE II. It was not, therefore, Mr. GREEN who was chosen in consequence of the vacancy which was caused by the death of Sir WILLIAM BLIZARD, but Mr. CALLAWAY, the Assistant-surgeon of *Guy's Hospital*. Although, therefore, we were wrong with respect to the name of the gentleman who was last week stated by us to have been elected, still, so undeviating is the College in showing its unjust and pernicious partiality towards the surgeons who are connected with the hospitals of this metropolis, that not a little of our argument was inapplicable to the occasion. If Mr. KINGDON and hundreds of others had not been turned aside to give place to Mr. GREEN of *St. Thomas's Hospital*, they were made to yield to the preference which was shown for Mr. CALLAWAY of *Guy's Hospital*. To such a barefaced and scandalous extent is this practice of choosing the hospital surgeons carried, to the exclusion of other gentlemen of acknowledged attainments, abilities, and industry, in the profession, that out of the twenty-one Councilors who at the present moment sit in the College, the enormous number of thirteen are holding office in the various hospitals of this metropolis, and are conferring in conclave in the College.

their regulations for the government of the students who belong to their own institutions as well as for the government of the gentlemen who are connected with the private schools. Seventeen out of the twenty-one Councillors belong to the "recognised" hospitals. What an astounding fact!

In defiance, however, of these circumstances, the members of the Council have the effrontery to contend, that when a vacancy occurs, they elect the new member according to the seniority of his standing in the list of the commonalty. The gross and daring falsity of this assertion is evident from throwing into contrast the few hospital surgeons, with the many thousands of the medical commonalty who hold no situations in our public medical establishments. If it be a system of "seniority" or of "rote," let us see with what honesty it has worked:—

In London, and within a circle of ten miles around the capital, it has been calculated that there are nearly, if not quite, a thousand resident members. How happens it, then, if the rule of seniority be observed in taking the names as they stand upon the list, that a moiety of the entire body of the surgeons and assistant-surgeons of our hospitals should be seated in the Council at one time, and only four be selected from the remaining nine hundred and sixty-six members? These numerical facts are so damnable to the electoral proceedings of the Council, that it is unnecessary to expatiate on the infamous partiality which has been shown towards particular individuals and institutions. On some occasions, it is quite evident that the names of hundreds of members must be passed over at a single election, in order to reach that of an hospital surgeon, and having arrived at persons connected with their own institutions, seniority is then allowed to exercise its full influence in guiding the decisions of the Council.

Does our attention to the choice of the surgeons of *Guy's Hospital*?

Mr. ASTON KEY, Mr. JOHN MORGAN, and Mr. BRANSBY COOPER. Who is the assistant surgeon of that institution? Mr. THOMAS CALLAWAY. How many of the four occupy seats in the Council? Only one. Who is that individual? THOMAS CALLAWAY, the assistant-surgeon. In this election, therefore, the practice of election according to seniority has been observed, Mr. CALLAWAY being the senior member of the College.

This exposition will lead many persons to inquire, how it has happened that the three surgeons of the hospital, who are Mr. CALLAWAY's juniors in professional standing, occupy a higher station than himself, when it is well known that the whole four were the apprentices of the former surgeon of *Guy's Hospital*. Adequate information on this subject can only be furnished by our ancient friend KING HARRISON; but it is a well-known fact that on the election of Messrs. KEY and MORGAN, a scandalous attempt was made to nullify the claims and pretensions of Mr. CALLAWAY, and, subsequently, when Mr. B. COOPER was chosen, having served an apprenticeship there to render himself "eligible," after he had acted as an assistant-surgeon in the army, the office of assistant-surgeon in *Guy's Hospital* was then, for the first time, created. Mr. CALLAWAY received it, and the enrolment, it was hoped, would operate as hush-money on the mind and tongue of that gentleman. We apprehend that the wily treasurer was successful in his project, and it is now sufficiently obvious that the scheme was by no means an unfortunate one for Mr. CALLAWAY. Had that gentleman been excluded,—had he, through the instrumentality of calumny or intrigue, been cut off permanently from all official connection with *Guy's Hospital*,—is there a man in the profession who will not believe that such a circumstance would have been made by the majority of the Council in Lincoln's Inn Fields, the ground-work for visiting upon him a continuance of the

persecution; but Mr. CALLAWAY having become the assistant-surgeon of *Guy's Hospital*, the Councillors of the College leap over the heads of some two or three hundred members of the commonalty, for the purpose of bestowing upon that gentleman their smiling and corrupt partiality. Far be it from us to deny that the Council have a legal right to act as they have done. The charter has conferred upon them an odious power, and odiously do they exercise it. Ignorance gave them a bad law, and they have perseveringly resolved that its provisions shall always be executed with cupidity. There are, however, some members of the College,—no, we mistake,—there is one member of the College, who says that “it cannot be denied that the changes made of late years by the Council have been marked by increasing justice and liberality; and, to revert to the case in question” (the admission of Mr. KING to an examination for the diploma), “the Council in that case acted upon principles more liberal than the charter itself seems to have prescribed.” This language we quote from the letter of Mr. KING, which appeared in *THE LANCET* of September the 26th, the first Number of the current annual volumes. The introduction of seventeen hospital surgeons into a Council of twenty-one, the whole twenty-one having been selected from amongst upwards of 6000 members of the College, furnishes a beautiful “mark of increasing justice and liberality.”

This may not be an inopportune moment for referring to the attempt which was made by Mr. KING, in the letter already cited, to draw a contrast between the proceedings of the London University and the College of Surgeons, more especially as related to the election of professors in the former establishment, and the admission of candidates to an examination for the diploma in the latter.

Mr. KING is of opinion, that the College made a display of “liberality” in his own case, in admitting him to an examination.

But did not the Council know that he had gone through all the routine of academic costs and charges, and that as they could not expect that he would then pay any fees, as a pupil, in the hospital schools of London, it was evident that they would extract something from his pockets if they did not obtain the twenty-two guineas for the diploma? It was a god send to the Council, as it could not be pleasant to them that a gentleman who had been an *interne* of the *Hôtel Dieu* should practise in London as a surgeon, without being a member of the College; and yet Mr. KING considered that the circumstance of his having an opportunity afforded him by the Council of fooling away twenty-two pounds, and throwing the money into their pockets, was “a mark of their increasing justice and liberality.”

Extraordinary as is this opinion, Mr. KING is equally peculiar in his notions of justice with respect to the administration of affairs in the College and the University. In the one case the writer tries to test the conduct of the rulers at the head of the collegiate institution, by reference to the terms of the charter. In the other instance he makes no mention whatever of the deed of settlement, but relies on the speeches and professions of individual proprietors, who were amongst the earliest supporters of the University. Mr. KING is for the concours in medical appointments; and in a note which was inserted in *THE LANCET* of Oct. the 19th, professes to be glad that *THE LANCET* is “beginning to advocate the election by concours.” Why, *THE LANCET* advocated the concours long before Mr. KING took up his residence in London! This was the first journal that called upon the Council of the University to elect its professors by concours,—by competition, or wrangling. A similar call has repeatedly been made by us on the Council of the College of Surgeons, and many years since we joined in a petition to the Legislature, praying that the members of the profession generally, might constitute a majority in all medical elections.

When the Council of the University declined to elect by the open system of concours, we were not insensible to the force of the reasons which induced them to elect their professors in private, and under the authority of such information, regarding the candidates, as they were able to obtain from public and private sources. The University was altogether a new institution; it was an experiment on the public mind. Owing to the liberal principles on which it was sought to be established, all the host of bigots and fanatics of the day vomited forth their calumnies against it, and endeavoured to overshadow the prospects of its conductors. It was felt, therefore, by every person who was desirous that the spirit of the age should be liberalized, that a knowledge of science should be more widely diffused amongst the members of society, and that the literary reputation of the country ought not to be wholly centred in Oxford and Cambridge, that the failure of the University would be a national calamity. The most extreme caution, therefore, on the part of the conductors was demanded, not only in the election of professors, but in the arrangement of every circumstance which was calculated to affect the permanent interests of the establishment. Who, then, shall blame the Council for having endeavoured, at the opening of the institution, to present to the public a phalanx of professors who had already acquired a certain extent of reputation, and had won, by their displays of industry and talent, a considerable share of the public confidence? The concours had not been tried in England; it was not understood here; and men of intelligence and reflection will allow that the Council were warranted in not attempting to sustain the experiment of establishing the University by the institution of what was to them a new experiment, the concours. But the moment that competition has commenced, the University confers the office of Professor on the successful competitor in an open examination, where the

minds and qualifications of the candidates are tested by appropriate measures. This is a symbol of what is to follow. As the chairs become vacant, and as the University maintains its hold on public opinion, there cannot be a doubt that the Council will open the professorships to the medical community, and confer the vacant offices on the most successful of the wranglers. But there is a wide difference between electing gentlemen in the slow succession arising from individual vacancies in the respective departments of an institution, and starting, at the very outset, with an entire body of unknown men, who, nevertheless, may have obtained their offices by concours. In the College of Surgeons the case is wholly different, and nothing can be more scandalous than the system of election in that establishment,—nothing more disgraceful than the absence of open competition in filling vacant seats in the Council. The charter neither stipulates nor interdicts, relative to the elections, further than by declaring that the Councillors are always to be selected from the commonalty. In conformity, therefore, with the liberal spirit of the charter, the Council were bound by their duty to the profession and the public, to select the best-informed men they could find among the members at large, and no proof of qualification could be presented equal to that which is derived from an exhibition in a concours. In neglecting such a fair and open trial for competitors, the Council have degraded the character of the institution; and, further, as the executive governors of a College of Surgeons, they have long forfeited every claim to the slightest share of the public confidence.

INSTEAD of furnishing proof of the truth of his base and slanderous allegation against the Editor of this journal, Mr. DERMOTT has forwarded to us five folio pages of what he calls an "explanation." That part of his communication which refers to the accusa-

tion that was so distinctly made in his paper in the *Morning Advertiser*, we here insert *verbatim* :—

"But to the point at issue, I certainly did make use of the following words—' Besides, ' Dr. Plausable had now by these means (his ' conversaziones) extended and improved ' his connections vastly amongst the go- ' vernors of a neighbouring hospital, a va- ' cancy for a physician occurred and I need ' hardly state that his parties ensured him ' success. He now sends occasional letters ' to THE LANCET, which it is scarcely neces- ' sary to state are always inserted and " well ' displayed." For let me tell you, gentlemen, ' that it is very seldom indeed, unless under ' some most peculiar circumstances, that a ' persons " communication" is refused pro- ' vided he has *plenty of the essential heavy ' metal*.* This is a very weighty reason ' with many Editors; provided too the com- ' municant drives his carriage, keeps a good ' establishment and is *therefore* considered ' as a most respectable and influential mem- ' ber of society. In a just state of society, ' &c."

"Looking at the paragraph, at what pre- cedes it, and what follows, as reported in the *Morning Advertiser*, it will be seen, in the first place, that I was speaking of the evil tendency of money upon society in general— and stretch the signification as much as you please, you cannot therein show that I lit- erally state that you have taken a bribe direct."

AS GEORGE DARBY DERMOTT has here made a clear and distinct confession of his guilt, we leave him to eschew the happy consequences of his own malignity and folly.

A word to the Editor of the *Morning Advertiser*. On the 20th of July last, the annual " Cartwright Dinner " was held at the Highbury - Barn Tavern, Islington, Mr. WAKLEY in the Chair. On the following morning a few sentences of a report of the proceedings at the dinner were published in the *Morning Advertiser*. It was therein stated, as a part of a speech made by Mr. WAKLEY, that he had said in his notice of the public press, " that the *Morning Advertiser* newspaper had neither scope, space, " nor talent, to espouse the cause of the peo- " ple efficiently."

In another part of the paper there ap- peared an editorial comment, in which Mr. WAKLEY was called upon, under a threat, to explain whether he had or had not used these words. The threat was, of course, regarded by Mr. WAKLEY as an invocation to silence. Had there been no menace, he would most cheerfully have stated that he did not utter one word or syllable injurious to the character of the *Morning Advertiser*. On the contrary, he most distinctly and un- equivocally declared that of all the morning papers the *Morning Advertiser* advocated, on the broadest and most liberal basis, the rights of the mass of the people. In fact, the editor of the *Advertiser* was im- posed upon, on that occasion, by a tissue of infamous falsehoods. Mr. BARCLAY, late candidate for the representation of York, and other gentlemen, addressed letters to the *Advertiser*, showing the inaccuracy of the statements in the report, and the Editor of the *True Sun*, who was at the dinner, gave a report of the proceedings at variance with that which appeared in the *Morning Advertiser*. That gentleman even offered his own personal testimony in proof of the fallacy of the calumnious statement. But there was one person who wrote to the *Advertiser*, affirming the accuracy of the words which had, in the first instance, been attributed to Mr. WAKLEY. That person was GEORGE DARBY DERMOTT, whose feelings towards THE LANCET have, for some time past, been those of bitter enmity, from his entertaining an opinion that his labours, as an author and a draftsman, were slighted by that journal. This was the witness.

The editor of the *Morning Advertiser* ought now to be convinced that he acted very harshly, if not unjustly, towards Mr. WAKLEY on that occasion. But it is quite true that a reformer, or the conductor of a journal, who pursues his course honestly and inde- pendently, cannot, by any possibility, escape false imputations; but, if he persists in his course in utter defiance of such imputa- tions, the labours of such a journal can be of no use to the public.

* These words were printed in *italics* in the *Morning Advertiser*.—ED. L.

IN publishing the letter from Mr. ROGERS, which will be found at page 256 of the present number of *THE LANCET*, giving an account of an inquest which has recently been held at Farnham, we should violate our own sense of justice and propriety, if we were to refrain from stating that Mr. POSTELLO does not appear to have incurred the slightest degree of culpability in connection with the decease of the child. In short, there is not a tittle of evidence in proof that the child was poisoned. Certainly the powder which was administered on the *Sunday* morning, was not the cause of death by poisoning on the following *Thursday*, and was assuredly not that which was found in the stomach of the deceased at the *post-mortem* examination on the following day. Mr. POSTELLO is entirely exonerated from blame, and it is an act of malicious cruelty to make him the object of suspicion or reproach on an occasion in which his conduct is wholly blameless.

CREOSOTE is now enjoying in London the vogue which it possessed one or two years ago in Paris, and, at an earlier period than that, in Germany. The various experiments made with this new remedy, and the different opinions prevailing with regard to its medicinal powers, induced the Royal Academy of Medicine in Paris to appoint a commission of its members, with a view of examining the several memoirs addressed to the Academy on this subject, and of performing for themselves experiments with this highly extolled substance. These trials have been concluded, and in a report on the therapeutic properties of creosote, made by M. MARTIN SOLON, on the 6th of October last, on behalf of the commission, it is stated that they do not at all confirm the character for success given to it by most of the authors who have written upon creosote. The commission, therefore, are inclined to believe, that its therapeutic powers have been very much overrated; but their investigations have led to the discovery of its use for the preservation of anatomical preparations. Thus a heart, a portion of epiploon, a portion of liver, and other preparations, were

placed in a jar containing a weak solution of creosote, in order to test its quality in this respect. The jar remained in the amphitheatre of the *Hopital Beaujon*, from the month of August last until the presentation of the report, when the preparations were still in a state sufficiently good to give an exact idea of the organs themselves, and the lesions by which they were affected. The commission concludes by stating, "that creosote, a substance very remarkable in a chemical point of view, has a peculiar action on albumine, which it coagulates very quickly; that it has an exciting action on the economy, but is not more efficacious than other means which we already possess; and, finally, that, dissolved in water, it may serve for the preservation of anatomical preparations."

On the report being read, M. ANDRAL junior remarked, that he had made numerous experiments with creosote, without obtaining satisfactory results. He said he had tried it in pulmonary phthisis, in cancer of the uterus, and in the various forms of leucorrhœa. In eighteen cases of pulmonary consumption, neither the cough, nor the diarrhœa, nor any other of the symptoms, was alleviated by its use. In cancer of the uterus, when used in the form of injection, it acted simply like any other astringent. M. EMERY, in addition to this, said that he had employed this substance in various cutaneous affections, and generally with the effect of exasperating the disease. M. VELPEAU also spoke on the subject, and stated that he had tried it two years ago as an external application to cancerous, scrofulous, and syphilitic ulcers. He observed that he regarded creosote as an excitant, and even as slightly caustic, but he considers the nitrates of silver, of mercury, and some other such substances, as much superior in remedial efficacy. Some of our medical brethren on this side of the channel, hold a very different faith from the general creed of the French commission.

DUPUYTREN'S MUSEUM.

THIS museum, which with much greater propriety might have borne the name of ORFILA than that of the great surgeon whose bust is placed over the entrance, was thrown open to the public on the 2nd day of

this month. It occupies the small gothic church which was formerly attached to the old convent des Cordeliers, which, like so many other buildings in France, has passed from the service of the church to that of the state. It seems strange enough, as one of our contemporaries has observed, that visitors should enter a museum of anatomy through the door of a Catholic church, but anomalies of this kind are so frequent in France, that the *morale* of the circumstance does not seem to affect or disquiet even the most steady advocates of "the present order of things." In fact, we know not where a better study of a true creed could be found, than among such exquisite evidences of creation. Here, indeed, men have "reasons for the faith that is within them." We shall defer anything like a detailed description of this establishment, until a catalogue is published, and the presses are somewhat better garnished. The creation of a few months, "*Dupuytren's Museum*" is, of course, at present very incomplete. It contains, however, already, about 1500 preparations, which are labelled with care, and arranged in a manner well calculated to facilitate their study. The greater part of these have been removed from the museum of the Faculty, and are highly interesting, as numbers of them refer to the "*Memoirs*" of the old Academy of Surgery; the rest have been prepared by the young anatomists of the school. The establishment of the museum reflects the highest credit on the zeal and perseverance of M. ORFILA, to whose exertions alone the medical public of Paris are indebted for an opportunity of studying the various morbid alterations to which the human body is subject, in the most complete manner. Should the zeal of the dean be seconded, even feebly, by the different hospital surgeons or physicians, the *Musée Dupuytren* may soon hope to rival or surpass any similar establishment in Europe.

HUFELAND'S ELIXIR.

Formula for a very efficacious Anti-catarral Elixir.—In the obstinate and frequently distressing cough which remains after the influenza, as well as in other chronic and catarrhal coughs, the celebrated German physician HUFELAND has found the following mixture of the greatest benefit:—

R. Extract. Card. Bened. 5j; Dulsamar. 9j; Aqua Fœnic. 3j; Lauraceras 5j. M. 60 drops four times a-day.

Under the influence of this mixture the cough diminishes in a few days and disappears. The author has also found it useful at the beginning of consumptive cough, supervening on common catarrh.

WESTMINSTER MEDICAL SOCIETY.

Saturday, Nov. 7th, 1835.

Dr. ADDISON in the Chair.

DEATH OF SIR D. BARRY.

AMONGST other subjects which engaged the attention of the Society this evening was the death of Sir David Barry, whose name circumstances had combined of late years to bring frequently before the profession, and who was consequently pretty generally known as a metropolitan physician. The decease of this gentleman was announced by Dr. James Johnson, in the subsequent observations, which were followed by remarks from several members, occurring in the order in which we now proceed to report them.

Dr. JOHNSON said the death of Dr. Barry had occurred within the last few days in a sudden and seemingly-mysterious manner. His professional services were well known to the Society, and of them he need not speak, as were many of the qualities which would render his loss severely felt. The facility with which he communicated his ideas, the fertility of his imagination, the brilliancy of his wit, and the poignancy of his satire, were all equally remembered; though he might add, with regard to the latter, that whosoever he wounded his good-nature was eager to heal. On Tuesday last, Sir David dined out in perfect health. After dinner he ate three pears and some nuts, and in the evening some cake, which he did not relish; afterwards he felt an uncomfortable weight about the chest. On the following day, on his way to the city, through the Haymarket, he was suddenly seized with excruciating pain in the stomach and loins, and faintness, and felt assured that he was dying. He (Dr. J.) was sent for, but being from home, his son attended, who found Sir David pale, chilly, and with the aspect of a person who had sustained a severe accident. Sir David was conveyed home, and at one p.m. on the same day he was visited by Dr. J., when he was still chilly, and a slight reaction had commenced. The pulse was bad, and was beginning to be developed. Sir David considered that his sufferings were entirely dependent on the presence of indigestible matter, and that this

would be removed by an emetic. He (Dr. J.) demurred to prescribe this, but Sir David urged its administration. He (Dr. J.) reasoned with his patient on the subject, pointing out that as the indigestible substance had been swallowed fifteen or sixteen hours since, without doubt it had passed the pyloric orifice of the stomach, and that an emetic would occasion considerable pain and inconvenience. He therefore wished to prescribe four grains of calomel, and one of opium. To this Sir David acceded, and he was directed to be kept warm in bed, and to have hot cloths applied to the stomach. At his next visit, two hours afterwards, he found his patient relieved, and more composed, his skin was warm and moist. A warm aperient was prescribed, and as it had not sufficiently operated at eight p.m., an enema was injected, which produced copious evacuations. Between the time of prescribing the aperient and administering the injection, Sir David felt better; his pulse had become better, and no symptom was present, indicating that his end was so near; nor did Dr. Copland, who saw him, consider his life to be in danger at half-past ten p.m.; he remained quiet until one p.m., when suddenly he expired, after getting out of bed. He was in the fifty-sixth year of his age. The post-mortem examination was performed on the following Friday evening by Mr. H. Johnson. On laying open the abdominal coverings, remarkable layers of fat were found between them and the peritoneum, the stomach and intestines were empty, and exhibited no traces of disease. On making an incision into the right side of the chest, an immense quantity of clear serum burst forth, but he (Dr. J.) was not a little astonished at finding the left side of the chest filled with water, and five pints of blood effused into the cavity of the chest, an aneurysm of the descending thoracic aorta being discovered, of the size of an orange, which had burst into the posterior mediastinum. The left ventricle of the heart was hypertrophied, and found to be upwards of an inch in thickness. On reflecting on the matter, now that Sir David's sufferings and the cause of his death were ascertained, he (Dr. J.) was extremely glad that he had insisted on the impropriety of using an emetic, for had it been taken, death must evidently have occurred during its action; and if an examination had not been permitted, it would have been extremely difficult to account satisfactorily for the fatal result.

Dr. Copland said that he had but little to say on these particulars. When he was sent for, he found Sir David still expressing a great desire for an emetic, but not consenting to be required he (Dr. C.) hesitated in pressing on him to wait until the consultation at eight p.m., when Dr. Johnson and Mr. McIntyre would also be

present. When he (Dr. C.) arrived, a few minutes after Sir David's death, he hesitated at first what step should be taken; but he found that the lips were perfectly blanched, and that it was impossible by pressure on the vessels of the neck to fill them with blood; the same phenomenon was present in the veins of the arms, indicating death from hemorrhage, therefore nothing was attempted at this period to be done in the way of treatment.

Mr. STREETER inquired of Dr. Johnson whether there was any valvular disease existing. (The answer was in the negative.) He was induced to ask the question, because his (Mr. S.'s) father had died from symptoms very similar to those affecting Sir David, and in his case valvular disease existed, and was recognizable during life. His father resided at Clapham, and retired to bed one day as well as usual; presently after he was heard to fall on the floor; on being found and placed in bed, he could not articulate; the pulse of each wrist was different in its beat from that of its fellow. He (Mr. S.) arrived at seven p.m., at about four hours and a half from the attack; the power of utterance was still absent, but the patient was evidently conscious. At midnight he died suddenly, apparently while awaking from a quiet sleep. On the following day the body was examined, when no disease was discovered in the abdomen; but in the chest, one to two pounds weight of clotted blood was seen, and a large quantity of blood had made its way into the posterior mediastinum.

Mr. H. JOHNSON offered to describe the condition of Sir David when he first saw him. He found him sitting with his head on the epigastrium, the seat of agonizing suffering. Sir David at once urgently requested that an emetic should be administered, but with this request he did not comply; an opinion against it also was maintained by his seniors on their attending, the impropriety of the step being also since sanctioned by the ascertained condition of the sufferer. He was then cold, the lips were blue, the pulse was small, the countenance portrayed intense anxiety and suffering, and Sir David felt convinced that he should die. The morbid appearances were those detailed by Mr. Johnson. He (Mr. J.) believed that aneurysm of the thoracic aorta was extremely difficult to detect, and that even the most elaborate medical inquirers had admitted that fact. Dr. Green, it was true, had, in an able article in the Dublin Journal, arrived at the conclusion that the morbid condition could be predicated, yet the indications amounted in his opinion to little more than a series of guessings. In rupture of the aorta into the pericardium, it was not generally considered that death must necessarily follow immediately after the accident, and in Sir David

Barry's case, several hours had elapsed between the accident and the termination of life.

Dr. CHOWNE said he was aware that Sir David Barry was impressed with the idea that he laboured under an affection of the heart. Was Sir David of the same opinion during the present attack?

Dr. JOHNSON replied that about four years ago Sir David called on him, and requested that he would examine his chest with the stethoscope, as he (Sir David) feared that his heart was affected; but at that time no disease could be detected, although it was not impossible that the hypertrophied condition of the right ventricle had already commenced. As Sir David was inclined to be stout, and one who might justly be termed a *bon-vivant*, though not irregular in his habits, he (Dr. J.) recommended him to live rather more abstemiously. The circumstances of the sudden death of a Dr. B.—were recalled to his mind on the present occasion. The doctor was rather an invalid, and he (Dr. J.) called to see him in the evening, when he found him taking his wine. He (Dr. J.) sat with him for about half an hour, when, all at once, without any evident cause, Dr. B. complained of pain in the head and stomach, and turned pale. Presuming that the doctor was fainting, he administered some brandy and water, which presently revived him, but, shortly after, the pain returned in the stomach and back with increased intensity, and in a few hours after he died. At the examination, a considerable quantity of blood was found effused from the rupture of an aneurysm, which no doubt burst when he (Dr. J.) was first sitting with him, and the faintness induced, arrested the hemorrhage, but at last the gush was too large to be thus checked, and death followed.

Mr. COSTELLO related the case of a young gentleman who was brought into the *Hôpital Dieu*, under the care of Dupuytren; who had, while fencing, the point of a dagger thrust through the pericardium, which corroborated the opinion, and in great measure served to lay the dispute that had long existed, whether such injuries were fatal or not. Dupuytren maintained that they were not always followed immediately by death.

A few other remarks followed, and then the subject dropped. The other discussions of the evening, as well as those of some other societies, shall find a place in our next number.

THE *Medico-Chirurgical Society* held its first meeting for the present session, on Tuesday evening last. A report of the proceedings shall be given in the next LANCET.

MEDICO-BOTANICAL SOCIETY.

Tuesday, November 10th, 1835.

EARL STANHOPE, President, in the Chair.

THIS being the first night of the session, on the President taking the Chair, an address of congratulation on his return to England after a long absence was read. His lordship, in returning thanks, assured the Society that he felt most anxious for its success, and that he should devote much of his time to promote its welfare, both from his love for botanical science, and from the great respect he felt for the medical profession.

Dr. SIGMOND then read an eulogium on the late Mr. Gilbert Burnett, which was ordered to be entered on the minutes of the Society.

Mr. JOHNSON read an address introductory to the opening of the session, pointing out the advantages which had resulted from the study of botany, by contrasting the present objects pursued in medical education with its state many years since.

A paper by M. GERMON was next read, on the application of the juice of the *Mandarin tree* in cancerous diseases. The remedy is to be brought into contact with the eschar alone; care being taken to prevent its absorption at the edges, from which the worst effects might follow. Its analogy to the action of arsenic induced M. G. to recommend the juice, and anticipate success from its employment.

LONDON MEDICAL SOCIETY.

OBSERVATIONS BY DR. RAMSBOTHAM, ON EXTRA-UTERINE PREGNATIONS, AND ON THE TERMINATIONS OF THE UTERINE VESSELS, IN CONNECTION WITH THE PLACENTA.

To the Editor of THE LANCET.

SIR,—As you have noticed in the last number of your journal some remarks I made at the *London Medical Society* on a case of extra-uterine conception, I shall feel obliged by your correcting the following trifling inaccuracies into which your reporter has fallen.

I stated,—not that there were only recorded five cases of extra-uterine pregnancy, but that I was only acquainted with five reported in our language, in which extra-uterine foetus had been extracted by operation through the abdominal parietes, and that none of those cases had occurred in Britain. The earliest is given by Mr. Wood,

of Nexis, W. I. (*Philosoph. Trans.* vol. 19, June 1697.) Mr. Bard of New York has furnished one. (*Med. Obs. and Inq.* vol. 2, March 1760.) So has Dr. Bell of Dublin. (*Med. Commentaries*, vol. 2, part 1, 1774); in which instance the gestation was twin; and both fetuses were removed at the same time. We have another by Dr. McKnight of New York. (*Mem. Med. Soc. Lond.* vol. 4); and a fifth by Mr. Baynham, Essex County Virginia. (*Med. Facts and Obs.* vol. 1, 1791.) I might have added a sixth, which at that time escaped my recollection. (*Philosoph. Trans.* vol. 41, 1741); in which a butcher, named O'Neil, in the County Tyrone, Ireland, extracted by incision a fetus, whose elbow appeared through an ulcerated aperture in the abdominal parietes.

I mentioned also, as your reporter states, that I had personally known ten cases of extra uterine conception, besides the one under consideration; but as he has made me affirm what could not possibly happen, you will allow me also to correct him here. Four of the patients died from rupture of the sac, as evidenced by dissection; three of these were tubal—the most frequent form of all the varieties;—and the other parietal, or as the French call it, “interstitial,”—in which the ovum is lodged within that portion of the fallopian tube which traverses the parietes of the uterus. Three women died during the process of aliteration, established for the purpose of getting rid of the putrid mass; and three have recovered,—two after the evacuation of the foetal body, piecemeal, *per rectum*; and the last, who had the fetus remaining within her when I last saw her (having conceived about 26 years ago), and who has, to my knowledge, borne three children since she became the subject of this irregular species of gestation.

In noticing my remarks also on Dr. Lee's description of the connection between the uterus and placenta, your reporter asks in a note, “Where does Dr. Lee state that the apertures [described in the uterine vessels in communication with the placenta] are at their extremities?” It is true that Dr. Lee does not use the word “extremities,” but in his paper on the connection between the uterus and placenta, published in the *Philosophical Transactions*, and reprinted in his essay on some of the diseases of women, we read, p. 203, “The semilunar or valvular-like edges of the vessels at their terminations in the inner surface of the uterus, are admirably adapted to ensure the effects of arresting the current of blood,” &c.; and in the letter from Mr. Osborn of the College of Surgeons, to him, which Mr. Kingdon has inserted in that paper (and whose opinion we may therefore fairly suppose that he adopts) we find the following passage:—“In every instance, the vein, having reached the inner surface of the uterus, terminated in an open mouth on

that aspect.” “But with respect to the veins, they invariably presented the same appearances, terminating in open semicircular orifices, which are closed by the apposition of the deciduous membrane, and placenta.” Again: “The preparation which accompanies this letter shows the termination of a vein on the inner surface of the uterus, and an artery of the decidua cut through, with the corresponding appearances on the surface of the placenta.”

Dr. Nimmo's report, also embodied by Dr. Lee in his paper, is to the same effect. “These (uterine vessels), instead of passing directly into the placenta, are distinctly seen applying their open mouths to the membrane of the placenta;” and Dr. Lee himself states that “Mr. Broughton after having re-examined the preparations on which Dr. Nimmo had previously made his observations, authorize I him (Dr. Lee) to state to the Royal Society that Dr. Nimmo's account was perfectly correct.”

I think, from these quotations, we may presume that Dr. Lee's opinion at the time they were published was, that the uterine vessels, in connection with the placenta, terminated by open extremities. I am, Sir, your obedient servant,

FRANCIS H. RAMSBOTHAM.

14, New Broad-street, Nov. 11, 1835.

COUNCILSHIP IN THE COLLEGE.

To the Editor of THE LANCET.

SIR,—Let Mr. Kingdon take all the benefit he desires from his “appeal” to the profession. “What's he to Heenba, or Heenba to him?” The Council of the College of Surgeons dishonestly exercise the power which they wield;—to share this power Mr. Kingdon aspires, and bases his claim on the same pretensions as have been advanced and acted upon by all successful candidates for the usurpation, and he now grumbles that he is denied the power of riding roughshod over his fellow members, and demands their sympathy that the power is refused him! The members of the College have not shown all the spirit which their declarations in 1826 justified us to expect; but they surely will not weep with Mr. Kingdon, he having sought for office by recognising the unworthy principle which excludes from the Council the very men whose support he now supplicates. Let this gentleman show cause for the inconsistency which thus marks his conduct. I am, Sir, yours respectfully,

A MEMBER OF THE COLLEGE.

London, Nov. 5, 1835.

MIDDLESEX HOSPITAL.

To the Editor of THE LANCET.

SIR,—Fully convinced that you are a zealous advocate for the correction and reform of all abuses in the medical profession, I shall feel obliged by your inserting in your valuable and independent periodical the subsequent remarks on a subject relative to the *Middlesex Hospital*.

On my first perambulation through the wards of that institution, I felt surprised at the small number, comparatively speaking, of students really belonging to the hospital. From what cause, thought I, can the fact emanate? Can it be for want of scientific practice or principles on the part of the attendant medical men? Certainly not. What then! The causes are to me sufficiently obvious: viz., a deficiency in cases, and an impossibility of witnessing operations. Mayhap, I shall render the latter point more intelligible by an illustration. I, accompanied by three other college students, went to the hospital, one day last week, with the view of witnessing an interesting operation—the excision of a very large inguinal tumour, which proved to be medullary sarcoma, and which was rendered more interesting from the hypothesis, that the femoral artery and vein permeated the tumour; but so far from seeing the operation, we could scarcely obtain a sight of the patient, that part of the theatre designed for the students having been previously occupied with a very few exceptions by unrecognised students, —*students totally unconnected with the hospital*. This, Sir, is one case out of many; but, why, I ask, are students first to be *admitted* to attend that hospital, and then to be deprived nay, robbed for it is nothing less, AND THAT WITH THE ASSENT OF THE MEDICAL AND SURGICAL STAFF, of a portion of the benefit supposed to accrue from their attendance, and for which privilege they have most amply remunerated the governors or functionaries of the institution? In conclusion, Sir, I can confidently assert, that, so long as the officers so blindly pursue their present course, so long will the number of students continue to decrease. I am, Sir, your obedient servant,

A MEDICAL STUDENT.

London, Oct. 26, 1835.

ST. BARTHOLOMEW'S HOSPITAL.

CONVALESCENCE FROM FEVER.—DEATH.—AUTOPSY.

MARY ANNE DOWLING, ætat. 24, but whose appearance rather indicated 40, was admitted into Mary's Ward, on the 2nd of July, under the care of Dr. LATHAM. On admission, her countenance was flushed, and

the cuticular surface was dry, and increased in temperature; tongue white, but red at the tip and edges; pulse small and rather sharp, computing 100; bowels constricted; considerable emaciation; she complains of great oppression over the forehead and eyelids.

Her habits have altogether been intemperate. She has been indisposed for four weeks, commencing with a bilious attack, to which succeeded rigors, pains in all her limbs, severe pain in the epigastric region, with great prostration of the animal powers. She has been restricted to her bed, has had leeches applied over the stomach, and has taken medicines. Prescribed, now, castor oil directly, and three grains of hydrargyrum cum creta every six hours.

3. The night was passed sleeplessly; she complains of still more exhaustion: the cuticle is apparently peeling off; pulse very small, feeble, and numbers 120; tongue moist at the edges, the centre being completely covered with a dark brown fur. The bowels have defected three times. Ordered to have six ounces of wine and strong broth. It is stated that if wine be not administered every hour, the patient must inevitably sink.

4. The night was passed without any sleep, but no delirium was noticed; her aspect and general appearance indicate yet more depression; the wine was increased to obviate absolute sinking; pulse 110, more feeble; teeth covered with sordes; tongue moist, though enveloped in a thin brown fur; three watery though fibrous evacuations were voided to-day. Let the head be shaved and a blister be applied, and let her have seven ounces of port wine.

5. Passed an exceedingly restless night. She presents the same languid and feeble appearance; pulse 104, with increased power; teeth covered with dark sordes; tongue white and moist. She turned from one side to the other this morning; bowels have excreted pretty freely; heat of skin somewhat diminished.

6. Tongue clean and quite moist; pulse 120, though very weak; requires wine, without which she appears to be quite lifeless; bowels not relieved to-day.

7. The *ressemble* augurs improvement, pulse 120, with augmented power. She was perfectly tranquil, without any delirium, during the night; tongue moist, with a fur in the centre; her condition continues to demand the steady and frequent repetition of wine. The bowels have evinced no action for two days. The pill to be omitted, and a dose of castor oil to be exhibited.

8. During the afternoon of the 10th she sank so low, that her pulse became imperceptible, her skin cold and clammy, and tongue dry; in fact she appeared *articulo mortis*. It was deemed expedient to administer four ounces of brandy mixed

with water, in the short space of an hour, under which influence she rallied; her skin became warmer, her countenance was flushed, and she passed a favourable night. A solid and not unnatural evacuation has this day been passed; tongue rather dusky, inclining to brown in the centre; aspect not very propitious; pulse 120, feeble; no evident delirium. Ordered eight ounces of brandy and one grain of the sulphate of quinine every second hour.

9. There has been no very remarkable degeneration of vital energy since yesterday; aspect ameliorated; tongue moister and less furred; pulse still very feeble, amounting to 120; the same quantity of stimulus resorted to at the same intervals, continues to be indispensable; the quinine has of necessity been omitted, after its third exhibition, in consequence of its producing a flushed countenance, and determination of blood to the head.

10. Has had little or no sleep; countenance dejected; three dark watery evacuations were voided during the night; the first of these was tinged with blood. She evinces to-day some tremour of the limbs; tongue moist; pulse 130, with decidedly less power; bears pressure over the whole abdomen without exciting pain. Brandy exhibited every hour to prevent dissolution; if wine be omitted longer than an hour, the tongue becomes dry; apply a blister to the abdomen.

11. Aspect improved, though her countenance is flushed; had no sleep; blister rose well; stimuli administered every hour as before, to prevent sinking; pulse 120, still very feeble; tongue moist, furred, red at the tip and sides. Three watery stools were passed.

12. Passed a favourable night; aspect indicates an improvement; articulates with more power; teeth free from sordes; tongue moist, with a white fur, red at the tip and edges; bowels constricted; wine still persisted in; during the last four days she has taken a pint of wine and eight ounces of brandy in the space of twenty-four hours. Let her have a mixture consisting of twelve grains of the carbonate of ammonia and three ounces of camphor mixture; a tablespoonful to be taken every two hours.

15. Countenance more cheerful; rested better; pulse 120; bowels not relieved; perfect absence of pain in the head, chest, and abdomen; the wine and broth resorted to every hour; the brandy has been discontinued during the last twenty-four hours; the mixture was likewise rescinded after the second dose, on account of its exciting

13. Aspect more progressive; stimuli produced no longer intervals; has had no sleep, but healthy dejection; pulse very feeble, numbering 120.

14. Wine and broth persisted in as before; bowels confined; tongue covered with a white

fur, but red at the tip and edges; pulse as in last report.

16. Complains this morning of severe pain in the abdomen, especially in the epigastric region; no alvine excretion; tongue unaltered, and there remains the same urgent necessity for stimuli. Five grains of rhubarb and one grain of calomel directly. A sinapism to the abdomen.

17. Immediate relief succeeded to the application of the sinapism; sustains pressure without pain; the powder produced one dark solid evacuation, anorexia; tongue still coated with white fur. Continue the wine as before.

18. Slept tranquilly; evinces a brighter and more intelligent aspect; the frequency of the circulation continues, with no augmentation of its power. Abdomen remains free from tenderness. Persist in the use of wine and broth.

Acute pain diffused through the right arm, which appears increased by pressure, and is unattended by any visible change in the condition of the limb; pulse stronger, from time to time, at different periods of the day.

19. Had a rigor in the night, which lasted for ten minutes, followed by great heat; bowels relieved; other symptoms unalleviated. She has since manifested at one time improvement; at another a decided aggravation of all her symptoms. She has occasionally been up and walking about the ward, and then relapsing into the same depressed state; but under the influence of medical treatment in watching and ministering to her various symptoms as soon as they became evident, she continued to linger on, though spending a miserable existence, until the 12th of September, when death terminated her protracted sufferings.

Examination twenty-four hours post mortem.

The following phenomena were observed:—*Head.* Contents of the cranium quite healthy.

Thorax. The pleurae were adherent; no serum could be discovered in either cavity; the lungs contained an unusual quantity of serum, and their texture was large and easily torn. The posterior portion of the inferior lobe was greatly congested. A quantity of fat was observed at the base of the heart, and about the origin of the larger vessels. Two ounces of straw-coloured fluid were detected in the bag of the pericardium.

—*Abdomen.* The peritoneum was perfectly natural. The mucous membrane of the stomach was red with blood, but no ecchymosis was discerned. The small opening of the stomach was contracted. The duodenum was deeply injected; there were some circumscribed patches of vascularity in the small intestines, but not a vestige of ulceration nor any enlargement of any of the mucous glands was to be discovered. The inferior portion of the small intestines was of

a deep-red colour; the cæcum and the commencement of the colon were of the colour of soot, dependent solely on the mucous membrane, which appearance was entirely removed on the separation of that tissue. The liver was mottled, and easily lacerated; the remaining viscera evidenced not the slightest appearance of diseased action having in any time disturbed their function.

FIBRO-ALBUMINOUS TUMOUR OF THE BACK.—OPERATION.—James Jackson, ætat. 55, was admitted under the care of Mr. EARLE, on the 10th of September, with a tumour which had existed about fourteen months, and occupied the hollow of the venter of the left scapula, projecting about two inches beyond its base towards the spine, where it exhibited itself in the form of a deep rounded swelling. He complained of an uneasiness from its existence, though the actual pain which he suffered was but trifling. He could draw his arm forwards on the chest, and backwards towards the spine, without difficulty, and he possessed the entire power of rotation of the arm in its socket. Repeated applications of leeches had been employed, with cold lotions and purges, but as no benefit resulted from this treatment, it was deemed requisite by Mr. EARLE and his colleagues to remove the disease by operation. Accordingly on the 3rd of October he was conveyed into the theatre and secured on the table, when Mr. EARLE commenced the excision of the diseased part, by an incision about seven inches in length, along the base of the scapula, which exposed the insertions of the muscles into that portion of the bone. These were then divided along the line of the first incision, and the tumour exposed. It extended forwards below the blade-bone and the ribs. The operator then dissected round it, beginning on the surface which confronted the ribs, in which part it was found to have advanced very considerably, and it was separated only with great difficulty from the scapula, partly by the scalpel, and in part by the finger. The difficulty which existed in this part of the operation, originated from the circumstance that very close contact subsisted between the tumour and the bone, which at one part was denuded of its periosteum and rough. On the removal of the tumour a very considerable cavity was exposed to view, the walls of which exhibited the appearance of a large, thickened, whitish cyst. The wound was slightly dressed, and slight pressure was employed on the scapula. The tumour was afterwards examined in the library, and its nature determined by Mr. KIRKMAN to be *fibro-albuminous*. The case is doing well.

NORTH LONDON HOSPITAL.

CONCUSSION OF THE BRAIN.—FRACTURE OF THE NECK OF THE SCAPULA.—James Ricketts, aged 44, was admitted, Oct. 2 under the care of Mr. COOPER, in consequence of a fall while painting the roof of a lofty room. The pupils were dilated, his pulse was slow, and he was affected with sickness and vomiting. After a copious bleeding his pulse rose. On being brought to the hospital he was partially insensible but could be roused by questions put to him in a loud tone of voice. The iris acted on exposure to light. Pulse 120. The head was kept in an elevated position and a cold spirituous lotion was applied to the scalp; his bowels were opened with calomel and croton oil, followed by a mixture containing the liquor ammonia acetatis sulphate of magnesia, and antimony wine. On examination the neck of the scapula was found to be fractured,—a kind of injury Mr. COOPER remarked, which was very easily detected through the medium of the coracoid process. The arm was put up with a wedge-shaped cushion in the axilla the elbow being at the same time well supported in a sling. This case went on very favourably; the patient recovered the full power of moving his tongue, and left the hospital at his own request. Mr. COOPER remarked that a fracture of the neck of the scapula generally occurs through the notch in its superior costa. The case he considered to be an interesting one, because it was attended with some symptoms resembling those of dislocation of the humerus downwards. The arm sinks, the shoulder drops, the deltoid is flattened, and the elbow lowered. But the humerus can be readily raised again, which is not the case in a dislocation. The elbow is not drawn away from the side, as in a dislocation, and the humerus, after being raised, falls again on being left to itself. The crepitus can be distinctly felt on lifting up the shoulder, and applying the fingers to the coracoid process.

REMOVAL OF A SCIRRHOUS TUMOUR FROM THE BREAST.—Ann Price, a married woman, aged 36, was admitted, Oct. 22nd, under the care of Mr. COOPER, with a tumour situated below the left mammary gland, and towards the edge of the pectoral muscle. It began to form six or seven years ago, when of course her age was not more than 29. As she suffered a good deal of lancinating pain in the swelling, which had long resisted iodine, and other medicines usually prescribed in cases of mammary tumour, Mr. COOPER recommended the patient to have the part taken away with the knife. Accordingly, on the 4th she

was brought into the operating theatre, when Mr. C. OPEN, assisted by Mr. QUAIN, made two semicircular incisions through the integuments, in a direction downwards and inwards, one on each side of the diseased mass, beginning with the lower one. He then detached the tumour from the surrounding connections, and removed it from the surface of the pectoral muscle, by cutting from the axilla towards the sternum. Three or four strokes of the scalpel readily accomplished this separation. Two arteries having been secured, the wound was closed with adhesive plaster, and a piece of linen was put round the chest. The arm to be kept quiet in a sling. In some clinical observations on this case, Mr. COOPER observed that the tumour had every appearance of being a true scirrhus, though the patient was only 36 years of age. The fibrous septa between the light-coloured semi-transparent scirrhous matter, could be seen with the naked eye. This opinion was also corroborated by the sharp, pricking lancinating pain which was almost continually experienced in the part for some considerable time before its removal. In this woman, however, menstruation had not ceased. In the axilla there is a small indurated gland, not much larger than a pea, which Mr. C. proposes to remove if the woman will consent to it. It is at present quite indolent, and has never given any pain. In removing diseased breasts and tumours of this part, Mr. COOPER recommended the incisions to be made in the direction of the fibres of the pectoral muscle. The lower incisions, he said, should be made first, because, otherwise, the bleeding from the upper cut would obscure the parts below. The tumour should then be detached from its connections all round, and finally dissected from its subjacent connections, beginning from the angle of the wound which is towards the axilla, and proceeding downwards and forwards. The chief bleeding is always from branches of the thoracic arteries on the external side of the wound. Sutures are for the most part unnecessary. Mr. Cooper thinks them disadvantageous, from becoming a source of irritation, and sometimes an exciting cause of erysipelas. No operations, he added, were more frequently followed by secondary hemorrhage, than those of amputation of the breast and removal of the testicle. When a breast of some magnitude has been removed, he recommends the application of a compress over it, with a broad piece of linen passed round the chest, capable of being drawn tight with packthread, in the event of hemorrhage. Thus the bleeding may be immediately commanded, as he knew, he

SIR H. HALFORD and BENJAMIN BRODIE failed to obtain for their diligent friend ROTHERICK, the vacant professorship of Materia Medica, at King's College, Strand. The medical department of the institution was in a declining state, and it was considered that, for once, private interests must give place to the public credit of the establishment. Dr. PARIS, therefore, on the score of his well-advertised name, was solicited to accept the chair, but the old gentleman coquetted so long on the occasion, that at length Dr. WEBSTER, a physician to one of the metropolitan dispensaries, was applied to, and that gentleman is now delivering the winter course of lectures on Materia Medica in the College, and, we hear, with great satisfaction to the class, which, however, was not, in point of numbers, so tempting as to induce Dr. PARIS to accede at once to the proposition of the Council. We believe that Dr. WEBSTER will fulfil the duties of the office with diligence. He is a conscientious man, and will unquestionably do his best to instruct the pupils. Moreover, another change would yet more depress the fame of the College, and will be avoided, if possible. It is whispered, that in addition to other fancies and reasons, Dr. PARIS did not relish coming after Dr. Hawkins.

SOLID NAUSEOUS MEDICINES.—*To the Editor.*—Sir,—Perhaps you will, through the medium of your widely-circulated and invaluable columns, make known to the profession an easy method of administering electuaries, or any species of nauseous medicine, when in a solid state. It is by taking a piece of confectioner's wafer, softening it by immersion in water, and enclosing the medicine therein. By this means the taste cannot be offended by the most unpalatable compound. I first observed the practice on the continent, and have since named it to one or two practitioners, who have adopted it with much benefit to the patient. The knowledge of this method, however, is at present confined to but few. I am, Sir, your most obedient servant, V. DANIELS. Brompton, Nov. 4th, 1835.

CORRESPONDENTS.

A LETTER has been forwarded to us for publication, containing the signatures of a number of gentlemen who state that they are the pupils of Mr. DERMOTT. As the document is without either date or address, it may be a fabrication. If it be not, we may state that although we respect the motives and zeal of the subscribers, those gentlemen can scarcely expect that we should allow an odious accusation against

THE LANCET to be made the foundation of [illegible] (I have a son, bestowing an eulogy on the calumniator in [illegible] who is well able to fill the columns of the slandered work. [illegible] as dispenser to a surgeon. Can you [illegible] of obtaining a suitable and comfortable situation for him? The address of our correspondent may be obtained at the Office.

We never undertake to preserve papers. Articles not inserted are destroyed.

The letter of *Humanitas* on medical attendance in the North Aylesford Union, shall appear next week.

The note of *G. M.*, if published in its present form, would be no voucher for the fact which the writer states. Our remarks, as he will perceive, applied to the hospitals. As the fact stated by *G. M.* is one of some historical importance, it certainly ought to be announced under the authority of the name of the lecturer. Shall the name and address be attached?

A report of *Mr. Ellis's* "reform" lecture has reached us, but not in time for publication this week. A commentary on the report, or the report itself, shall appear in the next LANCET.

An able professional Correspondent residing in the country says (and we here very will-

L. The lectures of *Mr. Preston* have nothing to do with medicine.

The communications of *Mr. Cheyne* and *Mr. Edwards* will be inserted, the latter as soon as space will allow. The requests relating to [illegible] neither of them be forgotten.

A Medical Student. The indentures mentioned would not be received. Proof of execution of proper indentures would, in case of their loss, be received.

If A Subscriber will read the original remarks, he will find that they denote a principle of high professional importance. Common justice required that the rest should not, under the circumstances, be rejected.

ERRATUM.—We forgot to point out to the notice of a correspondent, that the words "plumbe of lead," in one of *Orfila's* receipts for dyeing the hair, were a misprint for "plumbe of lead."

METEOROLOGICAL REPORT.

(Extract from a Meteorological Journal kept at High Wycombe.

Lat. $51^{\circ} 37' 41''$ North. Long. $31^{\circ} 45''$ West.)

Lowest 28. the 18th, 19th, 21st, 27th, and 29th.
Mean 43.98588.

Barometer.....Highest 30.13 .. the 16th.
Lowest 28.63 .. the 10th.
Mean 29.49924.

Number of days of rain, 18. Quantity of rain in inches and decimals, 6.06875.

Winds.—6 East; 3 West; 3 North; 5 South; 1 North-east; 1 South-east; 6 South-west; 6 North-west.

So cold and wet an October has not occurred since 1823, and the rain exceeded what fell in Oct. 1823. Indeed so much rain has only once, viz. in July 1834, fallen in any one month during the last twelve years and a half.—The maximum of the thermometer was upwards of ten degrees below that of last October. The barometer was lower than since October 1824, as regards the mean; but the minimum was equal to the mean of the like months of the years 1824 and 1825. A few days were fine, but the number of fine days was much less than the average.

NORTH-LONDON HOSPITAL.

CLINICAL LECTURE

ON CASES OF

DEFORMITY OF THE SPINE, PAINS IN
THE HEAD, NEURALGIC PAIN OF THE
STOMACH, AND GOUTY AFFECTIONS.

Delivered in the Session 1835-36.

By DR. ELLIOTSON.

DEFORMITY OF THE SPINE.—*Deformity.*—The first case I shall notice to-day, gentlemen, is one of deformity of the spine, partly resulting from weakness, and partly from strumous disease. The patient was a girl, aged ten years, admitted on the 27th of July. The account obtained from her was, that she had had a curvature of the spine as long as she could remember. About eighteen months ago she began to complain of shooting pains in the right foot and leg, and soon afterwards in the left. These were gradually followed by partial loss of motion and complete loss of sensation. She also lost the power of retaining her urine and feces. About a year ago she was admitted into St. Bartholomew's Hospital, under the care of Mr. LAWRENCE, where she remained four months, and during that time had two issues formed on each side of the dorsal part of the spine. She improved very much while in the hospital, and when she left had regained the power of retaining her urine and feces, and perfect sensation in the lower extremities, but she is still unable to use her legs for support or motion. In other respects her health is good.

On her admission here she was in a state of extreme weakness, and there were other curvatures of the spine beyond what the disease of the dorsal vertebrae had occasioned, while curvatures appeared to be owing to the want of power in the muscles to keep the body erect. It was this curvature which appears to have existed ever since he could remember. The disease of the

spine appeared to have been perfectly cured by Mr. LAWRENCE. To have attempted a restoration of her shape would have been fruitless, but there was an evident indication that improvement of her strength should be attempted, and for this purpose I ordered a cold shower-bath daily, and half a drachm of carbonate of iron three times a day.

On the 11th of August she had become considerably strengthened, her complexion was even rather florid, her appetite was good, and on the 15th the dose of carbonate of iron was increased to a drachm. On the 23rd she could move her legs freely, although only through a limited space. She was unable to bend any of the joints of the lower extremities beyond a small angle, but within that distance she could move them with the greatest readiness. Her complexion was improving. On the 1st of September she was much stronger, and her complexion absolutely florid. Her appetite was good, and she could now walk alone, though she was unable to support herself upright on her feet. This is an instance of the great benefit that may be derived in cases of curvature of the spine from debility, by the use of tonic measures, and, among those, certainly iron and the cold-bath rank the first. Had the disease not lasted so long, and the curvature not been so great, and had there not been, also, scrofulous disease of some of the vertebrae, extension might have been proper, but in this case I conceive it would have been useless.

I may mention here that I was greatly delighted lately, when visiting Paris, to see the beautiful plan of treatment adopted in an *Orthopédic Institution*. I visited that of Dr. BOYER, and of all the things that I visited belonging to the medical departments of Paris, nothing gratified me more; little, indeed, gratified me so much.

The plan adopted by this gentleman, and, I presume, by others, who have similar institutions in that capital, is two-fold,—that of invigorating the system as large, and that of restoring the misshapen parts as far as possible to their proper form. For the former purpose the patients are supplied with proper food, there are baths of various descriptions in the establishment,

and the persons under treatment exercise as much as possible in the open air. The hours of exercise recur three times a day, and unless in weather which is bad, it takes place in the grounds belonging to the institution. Tonic medicines were also given, and I took the opportunity of pointing out to M. BORVIER, as I did to M. LIGER, the great advantage that would arise from the employment of very considerable doses of the carbonate of iron. With the utmost liberality he assured me he would exhibit it in these diseases, for the purpose of ascertaining the superiority of rail doses. The other indication, that of restoring the deformed parts to their proper shape, is effected in the most agreeable manner. They practise a considerable number of gymnastic exercises, all of which have a tendency to extend the parts which are curved, while they strengthen the system in general. These exercises are infinitely varied, so that they are carried on with pleasure. The patients pass from one sort of exercise to another, and labour just as much as they themselves please. Some ascend ladders by the aid of their hands only, which ladders are suspended with a spring, so that the weight of the patient while hanging on the ladder, in ascending and descending, tends to bring the spine into a straight direction. Then they lie with their faces upon a sort of chair, which is placed on an inclined plane, and from a handle and thus draw themselves up the plane. They take hold of horizontal poles, and move about to a considerable extent, by means of their arms alone. I cannot detail the number of other contrivances and designs for the purpose of letting the body extend itself principally by its own weight. The patients are never allowed to rest upon their seat, or upon their bed. At dinner their *muscles support them in the stool* on which they sit to their amusements, so that the spine is supported—not pressed so as to have a tendency to curve; and the supports are more or less movable. In passing from the house to the grounds they use crutches, supporting them *one at a time, under the armpit, the elbows resting on the middle of the crutch*. As they pass from one gymnastic contrivance to another, they have these crutches *one with them*, so that they never rest for a moment on their feet, because while passing from one apparatus to another, while they use the crutches, their toes only touch the ground. Then their gymnastic exercises, which are quite a delight to them, are never continued long at a time, so that they could be fatigued. The patients practise them three times a day, and repose upon their backs I think for eighteen hours out of the twenty-four; and while in repose there is a moderate degree of extension kept up. They go on with their education while in this position, and from their

leaving this position for the purpose of gymnastic exercises three times a day, it is not irksome to them. They all seemed to be perfectly happy, and, in fact, in the highest spirits. The improvement which was effected by this mode of treatment, was manifested by the casts which had been taken of several young ladies, at the time of their admission, and at the time of their leaving the institution. Many had been quite cured, and many who had been greatly distorted were now comparatively but little deformed. In fact, a friend of mine, who accompanied me, with some other English medical men, met a young lady there with whom he was acquainted, and he was quite astonished at the improvement which had been made. The gentleman who superintended the establishment, Dr. BORVIER, appeared to be a most philosophic and amiable man, and I must repeat, that I greatly regret that there are not institutions precisely upon the same plan in this country. I say I regret, because I have not time to say, that notwithstanding the institution was but an hour's ride out of Paris, and my time was limited, I could not remain more than a scanty time to visit it, and the result which I experienced was participated in by all the English gentlemen who accompanied me.

PARIS IS THE HEAD-QUARTERS OF PARALYSIS AND DEFORMITY. *Chief of the Hôtel of Pains*. The next case which I have to mention, is that of a female, Ann BERTHE, aged 24, who was admitted on the 11th of August. About twelve months since she caught a severe cold, and was exposed to wet. This was accompanied by a kind of the tetanizing spasm. Ever since she has been subject to severe pain in her neck, head, and at the vertex, sometimes shooting down the chest. The pain was attended with heat. Cold applied to the face gave relief. About eighteen months ago she was admitted into an hospital, where she remained under treatment until her death again. During that time, as she was bedridden, the pain continued at the vertex, and at the back of the head, and at the face, and at the vertex, up to the armpits, and was once alleviated, from which she gained relief, but for a short time only.

It was quite certain that antiphlogistic treatment would not cure this patient. The antiphlogistic treatment had been fully employed, and from her pains, and the insuccessfulness of previous antiphlogistic treatment, it appeared to me that the exhibition of nuxvomica was likely to be of great benefit to her. There are a number of cases of pain in the head which yield to the exhibition of nuxvomica, and not to antiphlogistic means. These are cases in which, as in the present instance, there is painness, debility of body, and feebleness of pulse. The painness and feebleness here might arise from the strong

antiphlogistic means that had been employed; but as those had done no good, it was highly probable that measures of an opposite description might; but as the pain appeared seated in the periosteum, outside the head, and perhaps also in the dura mater within, I resolved to give her the benefit of what is of great use in these affections, the hydriodate of potash. She therefore took it in solution, with the carbonate of iron three times a day. She began with about three grains of the hydriodate, and two drachms of the carbonate, three times a day. On the 29th of August she was gaining her strength fast, as well as her colour and appetite. The quantity of the carbonate of iron was increased to half an ounce, and the hydriodate of potash was now as much in quantity as to give one to every dose. On the 1st of September her pain was less violent and her strength greatly improved. On the 12th the headache was less, her complexion absolutely florid. Up to the 17th the headache was daily decreasing in severity, and she slept well, and on the 29th she was discharged perfectly well, free altogether from pain, having complete possession of her strength, and presenting a fine florid complexion.

In chlorosis it is a very common thing for females to experience violent pain in the head, and loss of blood only makes this pain worse. The mode in which I discover the treatment necessary in such pains, is to observe the colour of the face, lips, and tongue, and the character of the pulse. If the redness of the face, and weakness and want of body in the pulse, I conjecture the case to be one which, like chlorosis, indicates the adoption of treatment which is calculated to restore the quality of the blood, and do not on any account think of employing antiphlogistic remedies. The pain of the head goes away, together with the palpatation, under the use of iron. But whenever I am satisfied that the pain is in the membranes of the head, and here it was in the periosteum, I give the hydriodate of potash, and it is just as successful in these cases as it is in others where there is no degree of paleness. The two remedies, combined together, appeared to be indicated, one by the state of the constitution, the other by the head symptoms. Although I might have cured the pain by the hydriodate of potash, yet I do not believe that I should have done any good to the constitution by it, without giving the carbonate of iron; and knowing how useful iron was likely to be in one part of the complaint, I gave her the benefit of both these remedies.

SPASMODIC OR NEURALGIC PAIN OF THE STOMACH.—*Crescote*.—The next case is that of Catherine O'Keefe, aged 47, a married woman, who has had several

menstruated since Christmas. "About nine years ago she began to have attacks of spasmodic pain in the stomach, which occur at intervals, and continue for two or three hours, and always come on an hour or two after dinner. She has been salivated several times, and bled and blistered, but was never relieved. Nine months ago she began to feel pain and a sensation of weight between her shoulders, and a sense of burning along the oesophagus. At present she is quite free from pain, excepting when she takes food, after which her pain returns in the most agonizing manner." She can only lie on her back, and she is at all times easier in that position. The pain is always relieved by hot ingesta.

Now this was decidedly a case merely of spasmodic or neuralgic pain of the stomach, not constant, but occurring at intervals. It was not increased by pressure, nor by hot ingesta. Had it been an inflammatory pain it would have been constant, although perhaps worse sometimes than at others. The pain would have been increased on pressure, and by ingesta of all descriptions, but particularly by hot and stimulating ingesta. The pain it is true was always worse after eating, but not worse immediately after eating. Where the pain is inflammatory, the pain comes on immediately upon taking stimulating food. It is common in these cases of spasmodic pain to find more or less tenderness, but this is merely the result of the straining caused by the spasm, just as every one must have experienced after severe cramp in the calves of the legs. The part is found rather tender the next morning. Now I was determined to give her what I knew to be a good remedy in the disease,—*Crescote*. Her pain was always relieved by hot ingesta, and therefore a stimulating narcotic like *Crescote* appeared strongly indicated. I mentioned in a paper printed in the volume just published of the *Transactions of the Royal Med. Chir. Society*, that although *Crescote* is an admirable remedy in gastrodynia, yet that it does not produce those striking effects which attend its administration, in vomiting unaccompanied by inflammation; I therefore was prepared not to expect immediate benefit from the *Crescote*, nor, indeed, until I had increased it to a considerable amount. I began with two minims every six hours, on the 25th of August, and it was gradually increased until we had reached ten minims, given every four hours, without causing any alleviation of the pain. The dose was then increased to twelve, and then to fourteen minims, and then the pain began to lessen. Still, however, she had considerable pain, and therefore on the 22nd of September the dose was increased to sixteen minims. On the 25th the report states that she had scarcely any pain in the epigastrium; her appetite was

3rd of October she had only slight pain to walk from Carshalton to this hospital, occasionally. Still, however, she had some pain, and therefore I increased the dose of creosote to seventeen minims. On the 6th of October she was perfectly free from pain, excepting a very slight twinge occasionally, and on account of the *slight twinge* I made the dose eighteen minims, and from this time she was perfectly well. She was discharged on the 6th of October, full of gratitude, declaring that this was the first time she had ever taken any thing which did her the least good.

Now, in cases of gastrodynia, without inflammation, mercury is useless, and so is bleeding, both generally and locally. From the want of an accurate diagnosis, the remedies which are proper in inflammation may be improperly employed in cases where there is only spasmodic or neuralgic pain, and the remedies of spasmodic or neuralgic pain may be employed where there is inflammation, not only without doing any good, but, for the most part, doing mischief. We are the more liable to make mistakes in these cases, from the tenderness which is left between the nature of spasmodic pain; but if we admit that tenderness is not greater than the violence of the previous spasmodic pain, may enable us to account for, and gradually to remove the spasm, we may almost always neglect, and retard it, by the use of the remedies of inflammation, or by employing the remedies of spasmodic pain to drive the pain from the spasm, by attacks very severe, it will be necessary to employ leeches and blisters, but these will not prevent the return of the spasm.

COLICA PICTORUM.—Purgatives and Creosote.—The next case was an example of acute spasmodic affection of the lower part of the alimentary canal, caused by lead—an instance of colica pictorum. This case likewise illustrates the great power of creosote over certain derangements of the alimentary canal; not that it was of any service in removing the colic, but in removing one of the symptoms which the colic occasioned. We have had many cases of this disease in the hospital since it was opened, and in many a very rapid cure has been effected by the exhibition of strong purgatives, combining them with creosote, for the purpose of arresting vomiting and causing purgatives to remain.

G. T., aged 27, admitted on the 25th of September, a painter, was in the hospital last April for the same complaint, and was discharged cured. He has been working in a room for the last fortnight, with the doors and windows shut, using a paint which was made of turpentine and white lead. He was then seized with severe pain about the navel, constipation, and vomiting of everything he took. This morning he attempted

to walk from Carshalton to this hospital, but the pain became so severe that he fell down and was unable to move. He was brought to town in a cart. "The pain in the abdomen is excessive, but is relieved by strong pressure. He has had no stool for three days. There is great oppression; the tongue is white, and the thirst is great." Mr. Taylor ordered him scruple of calomel, which was to be repeated in three hours, and an injection containing two ounces of oil of turpentine into a pint of barley-water, and this injection was repeated, the first having produced no evacuation. The second produced a copious evacuation of black feces, without pain. On account of his pulse being full he was bled to a pint, and the blood was bluish and cuppy. Calomel was given him every five hours, and his bowels soon became freely opened, but one symptom remained, and that was the vomiting. He still continued to vomit everything he took. Notwithstanding, too, the free state of his bowels, he had considerable purpura, for which Mr. Taylor gave him half a grain of nuxom of morphia; the vomiting ceased, and creosote was employed.

He gradually got rid of all affection of the stomach, but the vomiting returned as soon as he was bled. So on the 2nd of October, a scruple of creosote in an ounce of water and a scruple of nuxom of morphia, and in that state the vomiting ceased, and he went out perfectly well on the 13th of October.

I want to lay this opportunity of mentioning a case of vomiting to which I was called in private practice, and which had existed for some time, reducing the patient to such a state of debility, that she was nourished only by nutritive injections, and was considered to be in great danger; but a few doses of creosote arrested the vomiting permanently, and she became perfectly well, but the case has been published, and therefore I need not again enter into a detail of it.

With regard to CLINICAL INSTRUCTION, it may safely be stated, that no mode that can be devised is more helpful to the student in acquiring a thorough knowledge of medicine—the term *medicine* including both medicine and surgery. The present era has been, and will continue to be, distinguished in all times for the great contributions made to this department of science. Its advantages are most obvious. The mind is far more difficult to be fastened on a subject when it is addressed only through the ear, than in the general systematic lecture, but what adds the advantage of other senses is in clinical instruction, is calculated never to quit the mind.—*Mr. Tynan's Advice to Students, Oct. 6.*

ST. GEORGE'S HOSPITAL.

CLINICAL LECTURE

ON

E P U L I S,

WITH REMARKS ON OPERATIONS IN GENERAL.

Delivered, Nov. 3rd, 1855.

BY SIR BENJAMIN BRODIE.

GENTLEMEN,—I will read to you the history of a case in which I have been operating. The patient, who is now fifty years of age, “has had,” as she states, “bad teeth for many years. Four or five years ago she suffered very much from what she considers to have been toothache, after which two of the back teeth of the lower jaw became very loose, and dropped out, and then, for the first time, she felt a tumour occupying the place of the lost teeth, apparently rising from the alveolar process. It was at that time firmly bound with the jaw to her face; it progressively increased in size, and at times smelt. I have given her a great deal of pain, occasionally bleeding so much that she has been considerably weakened by the hæmorrhage.” This runs the report, which proceeds to say,—“At the present time,” that is previous to the operation which I have performed, “the tumour occupies about one-third of the left side of the lower jaw. It is firmly attached by a broad base to the bone. It is ulcerated on the surface; covered as it were with a membrane, something similar to that of the gum.” There was no discharge from it when she came to the hospital, and it gave her no pain. She said that her grandfather had a tumour of the same kind, from which he actually died. When she was admitted into the hospital the tumour was hard, as it the greater part consisted of bony matter; but when I questioned her on the subject, she said that in the first instance it was of soft consistence. The tumour in some respects, as I will explain to you presently, differs from many of the tumours which go under the name of “*epulis*,” but, nevertheless, I believe it to be one of the same kind.

In order that you may fully understand this case, I propose to give you the history of this disease. I use the word “*epulis*,”—reading the *you* like *poir*,—because that is the usual mode of pronouncing the name, and the mistake has lasted so long that it is not worth while to alter it. We ought to call the disease “*epoulis*,” with the true diphthong, because it is derived from the Greek *ἐπὶ ὀδῶν*, on the gum. This being the name given to it, so far back I believe

as the time of Hippocrates, you might suppose that the disease was well understood, and that, at any rate, you would find a good account of it in some writer or other. However, I have looked in vain in books for a history of the disease, or the mode of treatment necessary for its cure, to which I could refer you, and find that there really is none. I looked into Mr. SAMPSON COOPER'S Dictionary of Surgery, because that gentleman has taken great pains to collect whatever has been said on surgical subjects, and I think that if there had been a good description of the disease, he would have found it out. But his account is this:—“*Epulis*, a small tubercle on the gums. It is said sometimes to become cancerous. The best plan of cure is to extirpate it with a knife.” I then thought that I would look into an older authority, and turned to Hislop's “*Surgery*,” published more than a century ago. He says that “*epulis* are mild, and not cancerous; they may be removed by ligature, by caustic, and by the actual cautery.” This is the substance of what he has to say on the subject, though his account occupies perhaps two-thirds of one of his quarto pages. I have looked to other books, but I can find no history of it there; and, consequently, in order to give you the history, I must refer to cases which I have seen myself. I have seen a great many instances of the disease, and I dare say that I can furnish you with a correct account of its character.

This disease, according to my experience, occurs generally in women. Why it should do so I do not know, neither can I tell whether it is accidental or not. I think it hardly can be accidental, for during the many years that I have been in hospital practice, and during the shorter number of years that I have had a large private practice, it is improbable that I should have seen it much more frequently in women than in men, unless women really were most subject to it. Nevertheless I have seen it in men.

When you look at the disease in its early stage, it appears as if a part of the gum were more prominent than the rest; the prominent part is covered by a membrane like the gum, and when cut into, it is not very different in appearance from the consistence and structure of the gum itself; at least, so far as the eye can discern. On these accounts, as it looks like the gum on the surface, as it cuts like the gum, and as it is connected with the gum, so it is supposed generally to have its origin in the gum, and I cannot say that that is not its source in some instances; but yet I must own that in cases which I have had an opportunity of examining, it has appeared to me that the disease originated in the alveolar processes. I have observed that the disease is always situated by the side of one tooth, and generally a tooth is pushed out of the

socket as the disease advances. The history of the present patient tends to confirm this opinion, for she says that the teeth became loose and dropped out, and then upgrew the tumour. Here is a specimen *presenting it* of the disease, attached to the jaw, and in which it evidently appeared to have originated in the alveolar process. In the operation, I removed with the tumour the portion of jaw belonging to it; and I found in that part of the jaw which was sawn through and where it was not supposed that any tumour existed, that there was a substance exactly like the tumour itself, in the alveolar process. I sawed through the bone where I thought it was healthy, and there I found the socket of an alveolus, in which the structure was so exactly like that of the large tumour, that I thought it right to destroy this part. The tumour is at first small; as it advances the teeth drop out, and the tumour at last extends from one side of the jaw to the other. If the disease go on it will ulcerate and increase in size, and although in this woman it remained stationary, as any tumour may, yet it may go on to attain any magnitude. I have seen a tumour occupy the entire half of the lower jaw, so that the patient could not close the mouth, and it may go on further still, and run the course of any malignant tumour. Consider what any malignant tumour of the jaw will do, and that is what this tumour also may do. It may occupy the cavity of the mouth itself, press upon the cheek, and so interfere with the destruction of the fibres, so that you have a large indurated ulcer, with a tumour at the bottom of it. In short, it may run the course of any malignant disease. The patient may die worn out from profuse discharge, bleeding, vomiting, and the want of nourishment, for all these tumours about the cheeks, jaws, and face, ultimately produce these ill-consequences. The patient is unable to take food, and absolute starvation seems to be the cause of death in many cases. The tumour in itself, if it be allowed to remain, is just as bad as any carcinomatous tumour, or a tumour of fungous hæmatodes, there being this difference only, so far as the course of the tumour itself is concerned, that it does not make such rapid progress as malignant tumours generally do.

I have said that it may run a course similar to that of a truly malignant tumour, so far as the tumour itself is concerned. You will ask, "Why do I make this reservation; why do I say that it runs that course only in one respect?" A truly malignant tumour, such as scirrhus or fungous hæmatodes, contaminates the absorbent glands, which this tumour does not. The malignancy of the former tumours arises out of something in the state of the general system that is, in carcinomas, or in fungous hæmatodes. Cancer and fungous hæmatodes are not local diseases,

so that if you remove the disease where it shows itself, you find it rising up again afterwards, either in the part originally attacked, or, perhaps, in some distant organ of the body. If you remove fungous hæmatodes from the breast or leg, the patient may die of the same disease in the lungs, or it may show itself again in the breast or leg. So if you remove carcinoma from the breast, the patient may die of disease again returning in that part, or of disease in the lungs, the liver, or the uterus. But epulis is not like malignant disease in this respect; it does not arise out of any vice in the constitution, but is altogether a local malady. You may remove a cancer from the breast, and take away the sound parts beyond it, to considerable distance, and yet the disease will return. You may take away the tumour in epulis, assuring yourself that you take away the whole of it, and the tumour does not return. When the tumour has attained very large size, it often does not return after the operation, because it is too difficult to go out *the whole* of the disease; but if the tumour be of small size, you may remove the whole, and according to my experience, it will not return.

There are other tumours which possess this malignant character. Those take place which take up in the cheeks, which remain for years in the face, and when at last they begin to grow, produce large indurated ulcers, and frequently destroy life, belong to the class of half-malignant tumours. These tumours are generally considered to be cancerous; but if you take away the disease in the early stage, when it can be taken away *entirely*, there is no return of it. You need not be afraid, in the cases of the abscent glands being contaminated not of the disease showing itself in any of the viscera. Take away the whole of the disease quite beyond it, as there is no return. You can do no more in the patient with epulis; it is needless give her medicine, and try by that means stop the progress of the disease. You may eradicate the morbid growth, and the question left for us to consider is, how the eradication should be effected.

The mode of proceeding must depend on circumstances,—on the size of the tumour, on its extent,—and, partly, on its position. In the greater number of cases of the kind that I see,—in private practice at least, the disease is in the early stage, and, of course, then, the tumour is of small size and may be easily destroyed in the following manner.—First of all, all the teeth which seem in any way to interfere with the disease must be drawn. The tumour must be taken before you can operate. You thus expose the tumour, and, then, in ordinary cases, you proceed in the following manner. In cases where the tumour is broad, you

dropped out for some time, the alveolar processes have become absorbed, otherwise, of course they remain, and this circumstance you must bear in mind. I am now speaking of cases where the tumour is small. I place the patient before the knife, and then cut off the excrescence, so far as I can get at it. If the alveolar processes remain, of course I use such a knife as can be carried to the bottom of them; but if they have been absorbed, a straight common knife will do. You then wait for the bleeding to subside, and if there be a great deal of hemorrhage, you may postpone the next step of the operation to another day, when it may be done quite as well as on the first occasion. The next step of the operation is to apply the caustic potass to the surface of the bone from which the tumour arose. You may apply the actual cautery, or nitric acid; but I prefer the caustic potass, which answers the purpose fully as well as the actual cautery, and renders the patient much less. I think, moreover, that you know more exactly how far you go with the caustic potass than you do with the actual cautery, and be assured, also, for I speak from having employed it many times, that it answers the purpose perfectly. You should have a piece of caustic potass, with a point, so as to enter the alveolar process. It should be cut in the shape of a pencil, and be a piece of a tolerable length, and it should be fixed, at right angles, in the end of a pair of dressing forceps. Do not trust to your hands to hold it tight in the forceps, but let it be fastened on by a ligature, passed round several times, apply it to the surface from which the tumour had been removed, but if the alveolar process remains, take care that the caustic penetrates to the bottom of the process. Many prefer the caustic potass to anything else, because it does not coagulate the blood, and does not prevent the caustic from acting; and because, also, it will penetrate somewhat into the substance of the parts; whereas the nitric acid coagulates every substance with which it comes in contact and does not sink into it; it is more limited in its effects. You may conceive that the caustic potass is very likely to run about, to surround the cheek, to burn the tongue, and to involve parts beyond those which it is your intention to injure. It will dissolve in saliva, in the blood, and in the urine, and if it were to run about it would produce very great evil. Now, then, are you to obviate the effects of such an accident? Why, just as you always would avoid the effects of its application where you do not want it to operate. Whenever you employ it for the destruction of living parts, have something in hand that will act as an antidote to it, and stop its operation. If you use the caustic potass, you need only have some vinegar within reach, with bits of lint to dip into the vinegar, and apply to the neigh-

bouring texture. If you employ nitric acid, have some carbonate of potass, or chalk and water, ready to apply to protect neighbouring parts. You should never use caustic without having something by you that will destroy its properties, when the caustic is in danger of interfering with the neighbouring textures. There are some cases in which you apply the nitrate of silver (which is not a powerful caustic, and not much used for the destruction of parts) to the inside of the eyelids. Always have something at hand on such occasions to stop its operation, and the best antidote with which I am acquainted is common oil, which stops its action presently. But, to return.

Having removed the part with the knife, apply the potass to the surface, by which you will make a slough of the neighbouring parts, and destroy the surface of the bone. If the disease has descended to the alveolus, and the alveolar process is not absorbed, a narrow piece of caustic is to be introduced into the bottom of the process. This may be done at the time of excising the tumour, if there be not much hemorrhage; but if there be, then it is better to defer the application to another day; no harm arises from waiting, and you never can apply the caustic to much advantage when there is much hemorrhage, that was the reason why I only applied the caustic slightly to-day. You should always examine the part afterwards, in order to ascertain if you have left any portion of the tumour undestroyed. If you have, it may be removed by a knife, or by the caustic potass, after wards. It is not often necessary, but such, where the comfort or the life of the patient is at stake, you should exercise this precaution.

In this woman's case a good deal of the tumour was composed of bone, it had a hard bony base, and it was evident, from her account, that the bone began at the base, and had grown from thence, for she states that the tumour in the first instance was of soft consistence. Any tumour which is attached to bone is likely to have bone grow into it afterwards. I have seen a large fatty tumour, with a large process of bone, at last, grown on to its base. It was evident that the knife in this case would not take the tumour away. It might have been removed with a small saw. The cheek being held back, the saw might have been introduced, with the finger, so as to cut off the tumour; but these bone-nippers are much more convenient for that purpose; they take off the tumour quite as smooth as the saw, and in a much shorter space of time. They are simply a modification of the common bone-nippers, which are used for removing portions of bones at the ends of stumps. A pair however may be made, as I have had these made, specially for the occasion,—just adapted to the shape of the tumour, and fitted to embrace its face very

nicely. The forceps that I show you contains a mechanical improvement contrived by Mr. Weiss, who is certainly a very ingenious person, and whose numerous inventions have been of eminent use in surgery. They move with a double lever, so that much less force is required to take off a bony tumour than is requisite with the common nippers. They were only brought home two days ago, and, as I had not used them before to-day, I was surprised to find how little force was necessary to take off this tumour—a child, with these nippers, might have pinched it off with the forefinger and thumb—of course, therefore, these nippers are very advantageous to the operator.

Although there are many cases where the knife will not answer the purpose, and where the bone-nippers will, yet the latter will not always do, for in other cases the tumour has attained a very large size, and occupies so great a part of the jaw that the nippers are not safe as an instrument which must leave no portion of the tumour behind. Here is a specimen in which it would not have been safe to leave any part of the jaw unremoved. Here is another specimen, in which a portion of the jaw might have been left, but still it did not appear to me at the time to be safe that any part should remain. I dare say that in some of those cases in which the whole ramus of the jaw has been taken away, the disease has been of this kind, and, having occupied the whole of the jaw, the cure required that the whole of the jaw should be removed. In general, however, we are only called upon to take away a portion of the bone. The specimen I now present was taken from a private patient on whom I operated something less than a year ago; and here is another on which I operated about a year and a half ago. The latter patient came to London on account of the tumour on the jaw, a surgeon accompanying her to town. It appeared from the extent of the tumour to be doubtful whether it could be taken away without removing the whole of the jaw. I performed the operation in the following manner:—I first made an incision down the back part of the cheek, then another round the ramus of the jaw, and another on the front of the cheek. I then turned up the flap, and thus made a sort of window, or port-hole, in the patient's face; it was a sort of shutter; in fact, a circular flap of the skin of the face and cheek was detached, excepting at the upper part. This flap was then turned up so as to expose the bone, which was then separated from the healthy parts, on the inside and below, with a saw. Of course the teeth in the neighbourhood had been previously removed. The flap of skin and flesh afterwards came down into its place, the parts were brought together by the inter-

posed suture, as in the operation for hare-lip, the wound healed by the first intention, and in only about eight or nine days afterwards, I believe the patient was so well that she commenced a journey home—a distance of no less than a hundred miles. It was quite remarkable how slight an appearance the scar made in the face. You could just discern the three lines, but you could hardly tell, without looking closely at the patient, that anything had been done. I heard of this lady two or three weeks ago, and she then continued perfectly well, and a gentleman told me that you could hardly observe anything different in the face from what there was before the operation. You will think it remarkable that there should be so little disfigurement. You would suppose that a portion of the jaw being taken away, the side of the face would be shrivelled, and the chin turned on one side. This we should think is what ought to happen, but it is not what really does take place. The space from which the bone has been taken away becomes filled up with ligamentous substance, which keeps the bones asunder, at the same time binding them together. The patient feels that she has lost some of her teeth on that side, and she cannot masticate there, but she can masticate very well on the other side.

In the other patient the tumour was of a larger size still, and I performed the operation in the same manner; the edges of the wound were brought together by sutures, and all but a small portion united by the first intention. When I took the tumour hence—and what I am now about to mention is the most interesting part of the case, and, perhaps, one of the most important observations that I have made.—I found the alveolar process behind, having in it some exactly similar structure to that of which the tumour was composed, and I had cut through the middle of it; and when I looked at the patient's mouth, two days afterwards, I found, true enough, what appeared to be a tumour, occupying the alveolar process behind; and, more than that, I found a very small portion of the tumour attached to the bone in front, a small slice of it. This was easily taken off, and I then introduced a very narrow piece of caustic potash into the alveolar process behind, where the remnant of the tumour seemed to exist, and destroyed that remnant. I repeated this operation more than once, in order that I might be quite satisfied that the destruction of the part was complete. This made the cure a little more tedious than in the other case, where the subsequent application of caustic was not necessary. Some of the bone took place; some of the alveolar bone came out of the wound, and a small portion of it broke open the hole, notwithstanding these drawbacks, the cure was very soon completed, and the patient,

whom I saw only a few days ago, has since continued quite well. You can feel a strong ligament formed in the part where the bone was taken away. The bones are very little drawn together, for a strong ligament keeps them asunder and binds them at the same time. The chin is in the middle of the face, and if you look attentively at the patient, you see one side of the face a little different from the other, but this you would not notice except you looked particularly at it.

In the case of the patient in the hospital on whom I have just operated, I have, as I told you, already applied the caustic slightly; the application, however, may not be quite sufficient, and if so, I shall apply it again on another day.

OPERATIONS IN GENERAL.—As we have ten minutes to spare, I will make a few observations on another subject. A man came into the hospital, lately, with a large tumour on one side of his face, to have the tumour removed. I had seen him in the summer, and then finding the tumour comparatively small, I recommended an operation; but going out of town, I did not see him again until a short time back, when a day was fixed for the operation. He wished it to be performed on the third day, but before the second day came he went away; and, indeed, I do not know that he was very unwise in so doing, for I certainly had then great doubts as to the success of the operation. In fact, though I recommended the operation when the tumour was small, yet now the tumour was very large, growing at a great rate, having very much of the character of fungous Hematodes, and, apparently, considerably attached to the surrounding parts.

You will ask, if I did not recommend the operation, why did I propose to perform it? Why, because the man came in to have the tumour removed, and considered that nothing else could be done for him to avert death, though the operation would probably not prevent a fatal termination, and because also my colleagues thought the operation should be performed. I had little faith in the operation, but I thought it practicable, or if not, that I should discover sufficient in time to prevent any harm being done. The condition of the man could not be made worse, and might be bettered, but still I did not recommend the operation.

You will ask why it was an unfavourable case for operation. Why, first, the disease had very much the character of a truly malignant disease, it did not even seem to be a malignant, but much resembled fungous Hematodes, or something of that kind (for these tumours differ but very little), and it was growing at a great rate. Secondly, it was attached to the neighbouring parts, and, if not malignant, it was very likely that some portion might be left in spite of

all my care, and from which the disease might be regenerated.

Now allow me to say a few words concerning cases in which operations should or should not be performed. When I was a young hospital surgeon, I had a very high opinion of operative surgery, and I thought that in every case where nothing else could be done, an operation should be performed; but I think now, from experience, that we should be more circumspect in selecting cases for operation—that the danger of the operation and the chance of recovery ought to be well considered. A dangerous operation ought not to be performed, except where there is still greater danger to be apprehended if it be not performed, and not even then, unless the patient be made aware, at least in some degree, of the risk to which he is subjected. But the question, in many cases, is also one of ultimate success. A child has scrofulous disease of the knee, and disease in the lungs and mesenteric glands. The knee is very bad; you say that you cannot make a cure by medicine; you amputate; the stump heals; the internal disease directly makes more rapid progress than before, and the patient dies. The operation could not prolong life, which, however, it is always our business to extend as far as we can. A woman has a cancer of the breast; you amputate it; she lives even for two years afterwards, and you say that the operation has been successful; nay, if she live but a whole year, it may be supposed that she has gained something by the operation. But if the disease returns in three or four months, the patient gains nothing by the amputation. She has suffered great pain, and a certain extent of danger from which the operation is never free, and she dies at last of the disease for which amputation was performed. A great number of similar examples might be presented. You may say, "the patient was not made worse; no harm has been done." But I say that harm has been done, for the patient has undergone great pain and anxiety, as also have the friends, which might have been avoided. And society suffers a still greater harm. Every operation which fails, makes a deep impression on the minds of the patient's friends, and you may be assured that every such operation prevents two or three patients from undergoing an operation in cases where it might be successful. Therefore our duty to our patients, the credit of the profession, and the good of society at large, require us to avoid operations which do not hold out ultimate hopes of success. You must, I grant, perform many operations which eventually will not succeed, because you cannot always say before the trial is made that there is no chance of success; and you should give the patient a chance, where he himself desires it, and you really see that an operation offers one,

nicely. The forceps that I show you contains a mechanical improvement contrived by Mr. Weiss, who is certainly a very ingenious person, and whose numerous inventions have been of eminent use in surgery. They move with a double lever, so that much less force is required to take off a bony tumour than is requisite with the common nippers. They were only brought home two days ago, and, as I had not used them before to-day, I was surprised to find how little force was necessary to take off this tumour—a child, with these nippers, might have pinched it off with the forefinger and thumb—of course, therefore, these nippers are very advantageous to the operator.

Although there are many cases where the knife will not answer the purpose, and where the bone-nippers will, yet the latter will not always do, for in other cases the tumour has attained a very large size, and occupies so great a part of the jaw that the nippers are not safe as an instrument which must leave no portion of the tumour behind. Here is a specimen in which it would not have been safe to leave any part of the jaw unremoved. Here is another specimen, in which a portion of the jaw might have been left, but still it did not appear to me at the time to be safe that any part should remain. I dare say that in some of those cases in which the whole ramus of the jaw has been taken away, the disease has been of this kind, and, having occupied the whole of the jaw, the cure required that the whole of the jaw should be removed. In regard, however, we are only called upon to take away a portion of the bone. The specimen I now present was taken from a private patient on whom I operated something less than a year ago; and here is another on which I operated about a year and a half ago. The latter patient came to London on account of the tumour on the jaw, a surgeon accompanying her to town. It appeared from the extent of the tumour to be doubtful whether it could be taken away without removing the whole of the jaw. I performed the operation in the following manner—I first made an incision down the back part of the cheek, then another round the ramus of the jaw, and another on the front of the cheek. I then turned up the flap, and thus made a sort of window, or port hole, in the patient's face; it was a sort of shutter; in fact, a circular flap of the skin of the face and cheek was detached, excepting at the upper part. This flap was then turned up so as to expose the bone, which was then separated from the healthy parts, on the inside and below, with a saw. Of course the teeth in the neighbourhood had been previously removed. The flap of skin and flesh afterwards came down into its place, the parts were brought together by the inter-

posed suture, as in the operation for hare-lip, the wound healed by the first intention, and in only about eight or nine days afterwards, I believe the patient was so well that she commenced a journey home—a distance of no less than a hundred miles. It was quite remarkable how slight an appearance the scar made in the face. You could just discern the three lines, but you could hardly tell, without looking closely at the patient, that anything had been done. I heard of this lady two or three weeks ago, and she then continued perfectly well, and a gentleman told me that you could hardly observe anything different in the face from what there was before the operation. You will think it remarkable that there should be so little disfigurement. You would suppose that a portion of the jaw being taken away, the side of the face would be shrunken, and the chin turned on one side. This we should think is what ought to happen, but it is not what really does take place. The space from which the bone has been taken away becomes filled up with ligamentous substance, which keeps the bones asunder, at the same time binding them together. The patient feels that she has lost some of her teeth on that side, and she cannot masticate there, but she can masticate very well on the other side.

In the other patient the tumour was of a larger size, still, and I performed the operation in the same manner; the edges of the wound were brought together by sutures, and left a small portion unremoved by the first intention. When I took the tumour hence—and what I now show about to be removed is the most interesting part of the case, and, perhaps, one of the most important observations that I have made. I found the alveolar process behind, having in it some exactly similar structure to that of which the tumour was composed, and I had cut through the middle of it, and when I looked at the patient's mouth, two days afterwards, I found, true enough, what appeared to be a tumour, occupying the alveolar process behind; and, more than that, I found a very small portion of the tumour attached to the bone in front, a small slice of it. I repeated this operation more than once, in order that I might be quite satisfied that the destruction of the part was complete. This made the cure a little more tedious than in the other case, where the subsequent application of caustic was not necessary. Some of the bone took place; some of the bone came out of the wound, and a portion of it broke open the skin, notwithstanding these drawbacks, was very soon completed, and the patient,

whom I saw only a few days ago, has since continued quite well. You can feel a strong ligament formed in the part where the bone was taken away. The bones are very little drawn together, for a strong ligament keeps them asunder and binds them at the same time. The chin is in the middle of the face, and if you look attentively at the patient, you see one side of the face a little different from the other, but this you would not notice except you looked particularly at it.

In the case of the patient in the hospital on whom I have just operated, I have, as I told you, already applied the caustic slightly; the application, however, may not be quite sufficient, and if so, I shall apply it again on another day.

OPERATIONS IN GENERAL.—As we have ten minutes to spare, I will make a few observations on another subject. A man came into the hospital, lately, with a large tumour on one side of his face, to have the tumour removed. I had seen him in the museum, and then finding the tumour comparatively small, I recommended an operation; but going out of town, I did not see him again until a short time back, when a day was fixed for the operation. He wished it to be performed on the third day, but before the second day came he went away; and, indeed, I do not know that he was very unwise in so doing, for I certainly had then great doubts as to the success of the operation. In fact, though I recommended the operation when the tumour was small, yet now the tumour was very large, growing at a great rate, having very much of the character of fungous tumours, and, apparently, considerably attached to the surrounding parts.

You will ask, if I did not recommend the operation, why did I propose to perform it? Why, because the man came in to have the tumour removed, and considered that nothing else could be done for him to avert death, though the operation would probably not prevent a fatal termination, and because also my colleagues thought the operation should be performed. I had little faith in the operation, but I thought it practicable; or if not, that I should discover sufficient in time to prevent any harm being done. The condition of the man could not be made worse, and might be bettered, but still I did not recommend the operation.

You will ask why it was an unfavourable case for operation. Why, first, the disease had very much the character of a truly malignant disease, it did not even seem to be truly malignant, but much resembled fungous tumours, or something of that kind (for these tumours are larger but very little), and it was growing at a great rate. Secondly, it was attached to the neighbouring parts, and even if not malignant, it was very likely that some portion might be left in spite of

all my care, and from which the disease might be regenerated.

Now allow me to say a few words concerning cases in which operations should or should not be performed. When I was a young hospital surgeon, I had a very high opinion of operative surgery, and I thought that in every case where nothing else could be done, an operation should be performed; but I think now, from experience, that we should be more circumspect in selecting cases for operation—that the danger of the operation and the chance of recovery ought to be well considered. A dangerous operation ought not to be performed, except where there is still greater danger to be apprehended if it be not performed, and not even then, unless the patient be made aware, at least in some degree, of the risk to which he is subjected. But the question, in many cases, is also one of ultimate success. A child has scrofulous disease of the knee, and disease in the lungs and mesenteric glands. The knee is very bad; you say that you cannot make a cure by medicine; you amputate; the stump heals; the internal disease directly makes more rapid progress than before, and the patient dies. The operation could not prolong life, which, however, it is always our business to extend as far as we can. A woman has a cancer of the breast; you amputate it; she lives even for two years afterwards, and you say that the operation has been successful; nay, if she live but a whole year, it may be supposed that she has earned something by the operation. But if the disease returns in three or four months, the patient gains nothing by the amputation. She has suffered great pain, and a certain extent of danger from which the operation is never free, and she dies at last of the disease for which amputation was performed. A great number of similar examples might be presented. You may say, "the patient was not made worse; no harm has been done." But I say that harm has been done, for the patient has undergone great pain and anxiety, as also have the friends, which might have been avoided. And society suffers a still greater harm. Every operation which fails, makes a deep impression on the minds of the patient's friends, and you may be assured that every such operation prevents two or three patients from undergoing an operation in cases where it might be successful. Therefore our duty to our patients, the credit of the profession, and the good of society at large, require us to avoid operations which do not hold out ultimate hopes of success. You must, I grant, perform many operations which eventually will not succeed, because you cannot always say before the trial is made that there is no chance of success; and you should give the patient a chance, where he himself desires it, and you really see that an operation offers one.

though you know pretty well that even if it succeeds for a time, the success will not be permanent. Let me, however, repeat the important observation, for it is one not sufficiently borne in mind, that the failure of any operation prevents some patient or other from resorting to an operation where it would succeed, and thus every failure does harm to our art, and is injurious to society.

You will next say,—“Can you give us any rules as to when operations should or should not be performed?” I reply, of course there can be no rules, for every case may require a distinct consideration; but we may venture to lay down rules to the following effect:—A patient labouring under organic disease of any kind is a bad subject for an operation. If, therefore, you see a patient with disease in his knee, who has a fallow countenance, looking as if he had disease in the liver, and you find on inquiry that there is reason to believe that he labours under visceral disease, I should advise you not to operate in that case, for after amputation he would have a sloughing stump, and the wound probably would not heal. If a patient has a calculus in the bladder, and the bladder be much diseased, avoid the operation, for he will die. If he has a stone in the bladder and there is organic disease in the kidney (I am not speaking of a deranged action of the organ, or of alkaline urine, but, really, organic disease of the kidney), do not operate, for he is sure to die, not, perhaps, in the first week, but, probably, in a fortnight or a month. You should be very careful as to an operation in all truly malignant diseases. I do not allude to what may be called “half-malignant” diseases, but truly malignant affections, such as cancer or fungous hæmatodes, and the numerous varieties of those two classes. Surgeons formerly were very ready to amputate any woman’s breast which had in it a scirrhus tumour; now they are very careful how they amputate. I suppose that I do not recommend the operation for scirrhus in the breast in one case out of three score. You will see a vast number of these cases here, both good and bad, for all come to London to get the opinion of a medical man; and even in those cases in which I recommended amputation, the operation has much more frequently failed than succeeded, even with all my care. I have known several cases in which the operation has been performed by other surgeons, after I had recommended the patient not to undergo it, and in every one of these cases it has failed. Some of the patients have died immediately afterwards, and some have lived for a short period only. In all these malignant diseases the operation is attended with some hazard, for though the disease be in an external part, it is often complicated with visceral affection; and though the operation does not prove

fatal at the time, yet there is always very great probability that the disease will ultimately return. I do not say that you are never to operate in malignant diseases. That would be wrong, and very foolish, for sometimes the patient may be cured, and at other times a beneficial result may extend to one or two years. It is better for a patient to die of disease of the lungs, than of hemorrhage from a cancer of the breast. In some cases, then, you give the patient a respite, but you must be very careful and circumspect before you recommend an operation in malignant disease.

The simple operations form the best part of surgery.—I mean that they constitute that part of it which confers the most credit on the profession, and produces the greatest good to society. By what are called “simple” operations, how many diseases which would have become structural are nipped in the bud; and how many patients are cured of diseases which would become most distressing, but for these slight operations! And the small operations of surgery have this advantage, that for the most part they are not attended with danger. But even in small operations you are to be very circumspect. A patient may die of erysipelas after a small operation as well as after a great one. Be careful how you operate in seasons when erysipelas prevails,—when you hear medical men saying that they have had many cases of erysipelas. Take care that the patient is, if possible, always in good health, before you perform even a small operation. If the patient be a dram-drinker, or if he be one of the higher classes, and not a dram-drinker, but a person who indulges freely in wine, and is guilty of other irregularities, be careful in operating. Many persons who have been accustomed to live well, especially drinkers of spirituous and fermented liquors, will die even after a simple operation which you have been obliged to perform. I once saw a lady who—~~not a lady-like accomplishment certainly—~~ got drunk by herself in the morning, who died from diffuse inflammation of the cellular membrane, attended with sloughing, after the mere puncture of a very small encysted tumour. There is another class of patients in whom you should be careful how you perform operations, viz., women of the higher classes of society who are of a very nervous and hysterical habit; and, indeed, all persons who have a very bad state of the nervous system, or who belong to families in which mania has prevailed. Do not operate upon them except you are compelled to do so. I have known several hysterical ladies who appeared to have a peculiar circumstance connected with them, more than that of being very nervous, who have died, in a strange and unaccountable manner, after very trifling operations.

I have made these observations now, he-cause, having time, I thought it as well to take advantage of the circumstance to say a few words on this important subject.

WESTMINSTER HOSPITAL.

CLINICAL LECTURE

ON A CASE OF

EMPHYEMA.

Delivered November 3rd, 1835,

By DR. ROE.

EMPHYEMA.—*Pneumothorax Thoracis.*—*Autopsy.*—I intended to-day, gentlemen, to address to you a few observations on the important subject of clinical medicine; but the death of Charles Dyson, who has been for some months in the hospital, labouring under empyema, has given us an opportunity of exhibiting the morbid appearances which are found in that disease, and I think it will be more profitable to you to take advantage of this interesting occasion, to direct your attention to the symptoms under which this patient laboured, and the morbid appearances which the examination disclosed.

In the month of June last I was requested by our benevolent chaplain to visit this man in Regent-street, Westminster. I found him pale and emaciated, lying on his right side, coughing frequently, and expectorating a considerable quantity of frothy mucus. He told me that his case was considered to be one of consumption, and that he had been given over by his medical attendant. I recommended him to come into the hospital, which he accordingly did in July, and the following is the report of his case at that time:—Age 48; by trade a bricklayer, of a pallid countenance and sunken cheeks; complaining of cough, with frothy mucous expectoration, difficulty of breathing on moving in bed, but not so much so when he lies quietly; great debility and loss of appetite; his respirations were only twenty in a minute, but his left side moved very little on taking the full inspiration; his pulse was 86, soft and feeble. On percussion the left side elicited a very dull sound, both anteriorly and posteriorly, and over and under the left clavicle. The sound over the right side was tolerably clear. The respiratory murmur was inaudible at the base of the lung, over a small space close to the sternum, and on the right side it was bronchial and gurgling, and it was accompanied by a rattling sound. The heart's pulsations could not be perceived at all in its natural

position, but it was felt distinctly on the right side of the sternum. The left side measured about half an inch less than the right. Its intercostal spaces were obliterated, but no metallic tinkling could be heard. It could scarcely be said that any change of the sound elicited on percussion was produced by change of posture. His tongue was red and moist, and his bowels were torpid. He said he had enjoyed tolerable health until within the last five years, since which period he had been troubled in foggy weather with a cough of an asthmatic character, early in the morning and at night, but he had been able to follow his employment, until fifteen months ago, when he caught a violent cold. He states that he has never had pain in the left side, nor has he to his own knowledge ever had a pleurisy.

Now what disease does the history of this case indicate? The dullness all over the left side of the chest could only be produced by one of the following causes:—1st. A lung completely *hepatised*, or completely tuberculated. 2nd. An extensive *abscess* occupying the whole lung. 3rd. *Effusion* into the cavity of the pleura. Now the lung could not have become *hepatised*, nor could so extensive an *abscess* have been formed, without very severe preceding inflammation, but of which we have no notice in his history. It would have been a very uncommon thing to find one lung so totally tuberculated, as to be dull every where on percussion, and to be void of respiratory murmur, while the other lung was free from disease, and the expectoration exhibited no appearance but frothy mucus. Again, neither his countenance nor his cough was by any means indicative of phthisis, and though the lung had been condensed by the deposition of tuberculous matter, yet this could not explain the cause of the displacement of the heart. We therefore concluded that the dullness on percussion was not produced by any of these conditions, and very extensive *effusion* was the only remaining cause. That would satisfactorily explain all the phenomena,—viz., the displacement of the heart on the right side, the general dullness on percussion, and the absence of respiratory murmur every where except at the root of the lung, where it was probably pressed against the spine and was condensed by the pressure of the fluid. Now to this supposition there were these objections,—effusion of serum or secretion of pus is always preceded by inflammation, of the severity and duration of which the patient usually gives a distinct account. Now such things were noticed in this patient's history; but it is a well-known fact that the secretion of pus is not only a consequence of very acute pleurisy, running a rapid course, and terminating in the secretion of pus in ten or eleven days; but it also arises from that chronic state of inflammation of the pleura which

goes on without the patient being aware of its existence. Again, where the pleura contains fluid, ægophony is often heard. But the absence of ægophony in this case was satisfactorily accounted for by the immense quantity of fluid which his chest must necessarily have contained, if it contained fluid at all. You know ægophony is perceived in the commencement of pleurisy, or, rather, in the commencement of the effusion of serum, before the quantity effused has been considerable; as the effusion goes on, the ægophony disappears, and, as the effused fluid becomes absorbed, the ægophony reappears; therefore, the absence of ægophony constituted no ground of objection to the presence of fluid in the chest.

Now, as to the measurement, it is true that from whatever cause fluid becomes effused into the chest, in an early stage, the measurement of the chest is increased; but if it continues long in the cavity, and any attempt is made by nature to perform a cure, then contraction of the chest takes place, and you no longer find the enlargement. A change in the sound elicited by percussion is also generally produced by a change in the posture of the patient; and this is one of the most important signs, and one that is the most to be relied on, in examining effusion into the chest. The part which sounds dull in a depending situation becomes clear when the position is reversed, from the floating of the respiratory portion of the lung in the fluid. Now the absence of this sign in this case is to be accounted for under the supposition that the lung has been bound down to the spine, so that it cannot change its position. On whatever part of the chest, therefore, percussion is employed, it must be over fluid, unless we except that part where the lung was compressed against the spine. The sound therefore must every where be dull.

From the consideration of all these circumstances, it seemed almost certain that the patient was suffering from the effusion of a considerable quantity of fluid in the chest, and it was more than probable that this fluid was purulent, from the circumstance which I have just mentioned, that it is a *pute pleurisy*, which, more generally than anything else, terminates in the effusion of serum. However, to make the matter perfectly certain, I passed into the chest a needle, invented I believe by Dr. DAVIS of the *London Hospital*, which may always be introduced with the greatest safety. Sir BENJAMIN BRODIE, I have been informed, has introduced this needle into the cavity of the joints with perfect safety. It is made like a trocar, with a groove running through it, through which fluid may escape; and on introducing this needle into the chest in the case of Dyon, a turbid fluid flowed out, leaving no doubt that the disease was em-

pyema, or, in other words, that the cavity of the chest was filled with pus.

Now the death of this patient took place a few days ago, and we took out the diseased parts for the purpose of showing them to you, because you cannot form a correct notion of the manner in which this disease is to be cured, without a correct knowledge of its pathology.

The external appearances of the body were not unusual. There was very great emaciation. On removing the sternum, the heart was observed to be pushed completely over to the right side, being seated beyond the middle, and to the right of that bone. On removing the ribs of the left side, a large cyst was opened, which occupied the whole cavity of the *left pleura*, that viscous being compressed on the spine, and occupying a space scarcely bigger than a closed hand. This cyst contained about eight pints of sero-purulent fluid. The walls of the cyst were thick enough to allow of its being dissected from its costal attachments, and presented numerous corrugations. A band of dense membrane, as thick as the finger, extended from about the sixth rib to the lateral edge of the lower lobe of the left lung. It was this which, doubtless, prevented all the fluid from being drawn off in the operation. No connection could be traced between an abscess* formed between the third and fourth ribs and the cyst. The abscess seemed confined to the muscular substance. The *right lung* was studded with minute tubercles. The *liver* was granular, congested with blood, and myristicated. The *kidneys*, in like manner, were a little paler than natural. No other morbid appearances were observed. Here, gentlemen, are the parts. They have been steeped in salt, and are somewhat altered in colour. The lung is condensed and pressed down against the spine. The pleura is thickened, corrugated, and covered with layers of coagulable lymph. Here is the band passing from the lung to the inside of the ribs. This lung was not impervious to the air, for when it was taken from the body it could be inflated by a pair of bellows to some considerable extent. This other lung is much more solid than it ought to be, and by cutting it open you will observe some few tubercles in its substance. You observe, therefore, the morbid condition of these parts, — the thickened and inflamed state of the pleura, the dense state of the lung compressed against the ribs, and the distension of the cavity of the pleura with fluid, which pushed the heart completely over to the right side.

Now what is the mode by which a cure is to be effected in such cases? The cure takes place, it must be, by the removal of the pleura which covers the lung.

* This last point, perhaps not one of the least.

pleura which covers the ribs. You will therefore see that it is indispensably necessary, in order to promote a cure, to take care that the fluid be evacuated from the chest. You see always in a person who recovers from empyema, that the shoulder falls, and that the ribs are drawn in, so that the admeasurement of the diseased side of the chest becomes less than that of the other side, and you will see by drawings the very great contrast that exists between them. Well, then, if you bear this in mind, you will see the absolute necessity of getting rid of the fluid, and consider it as absolutely necessary to bring the pleura pulmonalis in contact with the pleura costalis.

Now, then, the first question is, how is the fluid to be got rid of? There are three ways of getting rid of the fluid, namely, absorption, spontaneous evacuation, and the operation of paracentesis. Now such a thing has occurred as the absorption of purulent fluid in empyema. BELLARD relates a case where it appeared that the fluid was absorbed, and as the patient had been taking a decoction of ammonia, he attributed the absorption to that medicine; but that is very rare. Spontaneous evacuation is not so uncommon, and it may take place in either of two ways,—by absorption through the pleura costalis, and discharging itself externally, or which more frequently happens, by opening a passage in the bronchial tubes, and discharging itself by expectoration. I met with a very singular case of this kind in the month of February last. I was called to see a servant living in South-street, Gressenden-square, and the symptoms under which she laboured were these—great difficulty of breathing, respirations forty a minute, frequent cough, expectoration of thick mucus, pulse 120, skin exceedingly hot, face flushed, great thirst, and loss of appetite. She was bled immediately, and took large doses of digitalis for three days, and at the end of that time, suddenly, an expectoration of most offensive purulent matter appeared. So offensive was it as to render it scarcely possible to remain in the room with her. She was a person of a peculiar temper, and it did not occur to me at the time to think it probable that this girl, after an attack of so short a duration as three days, had such a disease as empyema. I did not examine her, therefore, with the stethoscope, but I gave her three grains of the superacetate of lead, one grain of digitalis, and a grain of opium, three times a day, and to my great surprise the expectoration totally ceased in twenty-four hours. She recovered her strength, the difficulty of breathing subsided, and in three weeks from the commencement of the disease, she was able to go down stairs, walk, and take her usual diet. She then suddenly returned, and expectoration of the same offensive character took

place almost immediately. Hectic flushes of the cheeks followed, and a pulse exceedingly rapid and exceedingly feeble. I examined her chest, and found it almost everywhere duller than natural on percussion, and the respiratory murmur was only very indistinctly to be heard, particularly at the posterior parts. Nevertheless it was heard; but all around it, through the fluid; ægophony was very distinctly evident under the left scapula. She was then in so perilous a state that I consulted Dr. EDWIN HARRISON, who I believe to be the most skilful physician in London in detecting pulmonary disease, and he confirmed the opinion that it was a case of empyema. The opinion of Sir HENRY HALLORAN was asked by the wish of the girl's master, but Sir Henry, on the ground that it was not yet necessary, objected to what I very much wished to have performed, that is, the operation of paracentesis, as there was possibility of the girl dying, even were it performed. I did not press it against such an authority as his. I examined the chest very carefully, and found there was some tenderness on pressure. I applied cupping-glasses over it very extensively, and abstracted a small quantity of blood, only ten ounces. I supported her strength by strong beef-tea, and gave her as much as her stomach would bear of sulphate of iron. She immediately began to improve, and her strength increased. The expectoration still continued, but at the end of nine weeks it had almost totally ceased, the respiratory murmur had returned in almost every part of the chest, and the dullness of sound on percussion was not altogether gone, but very much diminished.

You will observe that this was a distinct case, in which there could not be any possible question of the spontaneous cure of the disease, empyema, by the evacuation of the fluid contained in the cavity of the chest, through the bronchial tubes; but whether the cure takes place in such cases by absorption, or by the spontaneous evacuation of the fluid, the cures are exceedingly rare, and if you wait for any considerable length of time, and the patient's strength becomes very much reduced, the operation of paracentesis may be performed with much less prospect of success. It therefore becomes exceedingly interesting to inquire what are the chances of recovery; or, in other words, what does the result of observation teach us in those cases in which paracentesis has been performed. Dr. DAVIES, who has performed the operation in ten instances of empyema, gives a table in the "Cyclopædia of Practical Medicine," in which he states that eight out of the ten cases operated on, recovered; five of the patients were under six years of age, one was aged between eighteen and nineteen, and two about twenty-five years old. Now chances are

proportions. Of those who were under six years of age, five cases recovered, and the reason is this, that the greater elasticity of the ribs, and the tender state, altogether, of the bones, makes them much more disposed to yield to the pressure, so that the pleura costalis and the pleura pulmonalis can be brought the more readily into contact, which is the point of cure.

You see, then, according to this, that the probabilities of recovery, when the operation of paracentesis is performed, are eight cases out of ten. In the medical journals of the 30th of November, 1833,* there is a case of a child, seven years of age, who was operated on by Mr. WOOLLEY, of Brompton, and he had the goodness to invite me to see the operation. It was an exceedingly weak and emaciated child, and presented the symptoms which I have just related, indicating empyema. The operation was performed, three pints of purulent matter were evacuated at once, and a considerable quantity of air entered at the operation, to which fact I beg your attention. The wound was suffered to heal, and the child was supported by nutritious diet, but in the course of three weeks there was reason to suspect that some fluid had again been secreted in the chest. The operation was performed a second time, and a smaller quantity of purulent matter was evacuated. Again air was admitted, and from that time the child went on gradually improving, so that in a short time his respiration became perfect on that side. The chest on percussion was perfectly clear, and the child is, I believe, at this moment, in perfect health.

Now, as to the time of operation, I believe that it should be as soon as possible after the disease is detected, and I think the instance which is before us is a clear proof of the correctness of that observation. When fluid is allowed to remain a considerable time in the cavity of the chest, it will of necessity compress the lung against the spine; and if adhesion of the lung against the spine takes place, you will see the very little probability there is of effecting a cure. It is, therefore, a matter of very great consequence to perform the operation as soon as you possibly can, because in the early stage it is almost certain that no adhesion of the lung has taken place, that the lung is free, and that the process of cure will, in all probability, go on without interruption.

Now the next question, and one of very great importance it is, is this, whether the wound is to be allowed to heal immediately, or the canula to be left in. The reasons for advising that a canula should be left in are these, that the sudden evacuation of so large a quantity of fluid is apt to produce very great debility; and that, if you were to evacuate the whole of the fluid at once, you

would allow a quantity of air to be admitted, which is considered to be highly dangerous.

Now with respect to the evacuation of a quantity of fluid. Here was a child in an exceedingly emaciated condition (I am now alluding to Mr. WOOLLEY's case), where all the fluid in the cavity was evacuated, without the child suffering in the least from the evacuation. Again, we have had several cases in this hospital, — one a very remarkable case, in which six pints of serum were evacuated from a man's chest, without any injury being produced from it. Certainly, therefore, as far as my experience goes, and as far as I have been able to examine the cases that have been published, I see no reason to believe that the sudden evacuation of fluid is, of necessity, at all dangerous. Nay, more, I believe that the space which the fluid occupies is filled, in a very great measure, by the air that is admitted, and the presence of this air does no harm whatever. In Mr. WOOLLEY's case, on both occasions of the operation, a considerable quantity of air was admitted, and neither time did any bad symptom follow. In the case of the man who was operated on in this hospital, a very considerable quantity of air entered, and occupied the place which six pints of fluid had recently occupied, without any symptom of inflammation supervening. But in the course of two or three days it appeared as if a greater accumulation of air had taken place. The lungs on that side afforded less marks of respiratory murmur, the sound on percussion was preternaturally clear, and the breathing became exceedingly difficult. Mr. WALSH, who is now practising at Worcester, devised a most ingenious little canula, to which a piston was attached, not much larger than this needle. This was introduced into the chest, and the air was pumped out. No inconvenience followed the use of the instrument, and the patient went on to a perfect cure. I see no reason, therefore, for concluding that the presence of air is necessarily a source of danger.

Now as to the place of the operation. LAENNEC advises that it should be performed between the fifth and sixth ribs; and the reason he gives for the advice is, that when the lungs are diseased, the attachment takes place more frequently between the superior lobe and the pleura, immediately under the clavicle, and between the lower lobe and the diaphragm, and the centre lobe is generally the freest. Again; it happened to LAENNEC to pass a trocar into what he supposed to be the cavity of the chest, without fluid following the instrument, and it was found upon examination that the trocar had not passed into the pleura at all. Now, as to the necessity of evacuating the right side you must always remember that sometimes the liver is very greatly en-

* See LANCET, No. 535, page 556.

larged, and rises a great way into the region of the pleura; and as dulness of sound on percussion may often arise from the liver being pushed up, and without any fluid being present, it will be necessary in performing the operation on the right side to be very cautious, remembering that you are in the neighbourhood of the liver, but you will be almost certain to pass the instrument into the cavity of the chest, if it be introduced between the fifth and sixth ribs.

But this is not all. Adhesions frequently take place between portions of the lung and the ribs, and, therefore, even this direction is not sufficiently minute. In Mr. WOOLEY's case the lung adhered posteriorly, almost completely, so that on putting the ear to that part of the chest, you heard the respiratory murmur distinctly, but as the ear was brought forward, you found the respiratory murmur was almost inaudible. It therefore became necessary, instead of puncturing between the fifth and sixth ribs, close to the *latus sinu dorsi*, to bring the instrument still further forward, and to choose that part where all sound of respiratory murmur was absent. Therefore, before you attempt to perform the operation, you ought to examine with great caution, and ascertain that no respiratory murmur is present, and to be perfectly aware of the possibility of adhesion between the lung and pleura.

Now having said so much upon the nature of the disease, and the mode which is adopted in order to effect the cure, we will conclude the history of Dyson's case:—On the 9th of July a flat trocar was introduced between the fifth and sixth ribs of the left side. On pushing it in, at first it seemed to carry the pleura before it, for on withdrawing the trocar from the pleura no fluid followed; but by plunging it suddenly in, the pleura was punctured, and about twenty-eight ounces of a turbid yellow serum, with flakes of floating lymph, were thrown out. The chest emitted no clearer sound after the operation had been completed than it did before. On the 11th, the patient is reported to have remained much in the same condition; his breathing was somewhat good, and his general health was improved, but the left side was not in the least degree clearer on percussion than it was previous to the operation. Severe ptyalism came on after that, from a small dose of calomel and rhubarb given on the 14th, the effects of which continued to the 31st, after which time his general health seemed daily to improve, and he was able to sit up for several hours in the course of the day.

Aug. 15th. He is reported to have remained much in the same state. Since the 11th, his breathing has been quieter, and he has much improved, but the operation has taken place on the 15th. On the 1st of September he was very troublesome, and his

breathing somewhat short. On the 7th of September he was ordered iodine and hydriodate of potass. On the 27th of September a tumour was observed, between the fifth and sixth ribs, on the left side, soft, elastic, and fluctuating, and of about the size of an orange. BACON's needle gave evidence of purulent contents. A seton needle was passed through it, armed with a skin of silk, and the contents of the tumour were evacuated. A discharge was kept up, supposing the tumour to be connected with the interior of the thorax. Four days afterwards he was reported to feel much easier. The seton went on discharging, but not in such quantities as to warrant a supposition that it communicated with the chest. The discharge was of a thin purulent character, and the patient now seemed to be losing strength daily. On the 15th he was considerably worse; he could not then sit up, and he suffered much from difficulty of breathing. On the 19th there was lividity of the countenance, blueness of the lips, coldness of the extremities, and depression of breathing, which symptoms increased until the 22nd, when he died.

The one thing of chief importance in this case was, that, when the operation was performed, though such a considerable quantity of fluid was in the cavity of the chest, only about eight-and-twenty ounces were withdrawn. We felt at a great loss to account for this, for there was not the slightest doubt that a great quantity of fluid still existed in the cavity. We thought it possible that the circumstance might be accounted for by the pleura having been sacculated. You will find cases published by Dr. TOWNSEND in the *Cyclopædia of Practical Medicine*,—there are one or two mentioned,—in which the adhesion took place at different parts, forming three or four distinct cysts containing fluid. We thought this might have been the case here, for on passing the needle higher up, a short time afterwards, the fluid again escaped, showing clearly that there was still a considerable quantity remaining; but I now believe the explanation of all this to be, that, from the position in which the man was lying, the canula must have come against this band, which, as I have already shown you, existed, and which prevented the evacuation of the fluid. But you may ask then,—“Why not have performed the operation again?” Why, the reason was this; the man took two grains of calomel, combined with ten grains of rhubarb, to open his bowels, through which ptyalism came on, and the man became so exhausted as to make it evident that all hope of recovery was gone; we did not, therefore, think it right to submit him to the further pain of another operation, because, even though we had succeeded at this time in evacuating the fluid, it could not have been attended with success. His strength was then supported

as much as possible, and nothing more was done than to alleviate, as far as we could, symptoms as they arose, until his death. I must, however, say, that if a similar case were to occur again (and this is admitting that we did not do all we might have done), I should certainly perform the operation, because I believe there could be no possible hope of curing the man except by the evacuation of the fluid from the chest.

ON THE

TREATMENT OF FRACTURES

WITHOUT THE AID OF SPLINTS.

By W. C. RADLEY, Esq., Surgeon, Newton Abbott, Devonshire.

(Concluded from page 251.)

THAT donkey-like emulation which makes "every ass think his own bray the best," would be extremely diverting, were it not true that struggles for place and precedence cause the great interests of humanity to be neglected or forgotten in the contest. In our noble profession it has long appeared to me, that whatever is written, which does not either directly or indirectly tend to the alleviation of suffering, is so much time wasted, and so much talent misapplied.

It is sickening to observe the rage with which novelty in medical science is pursued, while every-day cases are little understood, and therefore ill treated. Yet in spite of neglect, how frequently do we discover cases that have gone on unassisted, or have even been maltreated, which, with a little setting right, have ended happily! The *vis medicatrix nature* in the case of fracture, — a cause of suffering that daily furnishes abundant sources of observation, and for the cure of which so little has been done in the way of improvement since the days of Hippocrates, — is that portion of our art to the consideration of which I am now striving to direct attention. How often have I seen accidents made worse by meddling ignorance, or by the supererogatory offices of mistaken aid, yet ultimately triumph over all those retarding checks! This voluntary power of reparation is the true *magni Dei datum* to human nature, and "not cinchona bark," as a popular doctor once said. This power, however weakened, is always ready to assist us in surgical curations, and only waits to be guided or followed aright, to fulfil our intentions.

In the former part of my paper, cases of fracture in a middle-aged man, in an old and feeble woman, and in a very robust subject, were detailed, all of which were cured by the splintless method.

CASE 4.—The next case I shall mention occurred in August 1830, in a weak little

girl, about five years old, who was being carried in the arms of her sister, when both fell together, and the younger had her thigh simply fractured. The name of the child was *Towse*, and she lived in Newton Bushel. The bones were brought into apposition on a pillow, a bandage was applied, and some isolated slips of thin mahogany *renvers*, were lightly placed here and there over the course of the fracture, — for show, not for use, not exerting any effect. My reason for placing them so, was to propitiate the ignorance and prejudice which always strenuously contend for retaining old forms. I thus affected at that time to do as others did; but not so now. The child remained under the evaporating action of a moist bandage, in an easy state, for four days, sometimes half sitting, resting on her elbow in bed, and playing with her fellows. She ate and drank as usual, and slept without disturbance, for the limb was placed in the natural position, which I in a great degree had let her choose at the first, and which she said was easy to her. Would she have so lain at ease with her little thigh outstretched upon a splint? Or even with a rather tight bandage around it? Certainly not. Where there is the least feeling of restraint in such cases, I have never found ease. Observe a child asleep, and note its natural and "easy positions." What an admirable passage is this on position in fractures! — "The most easy position of the limb is that which is usually chosen by a person who is sleeping; for then all motion is suspended, and every part assumes that posture which is most congenial to the limb." This passage presents a foundation for a superstructure of rational arguments in favour of sound practice in the treatment of fractures. — But sound reasoning, and a simple, natural, and therefore a correct practice, founded thereon, are very different things; for Mr. S. Cooper and other surgeons recommend the thigh to be put in the *straight* position of Dessault, — a position which must be irksome to many, because it is unnatural to those who through weariness retire to rest. It is not the position of the tired sleeping child, who is almost bent into the form of a ball. But to return to my little patient.

An evil-minded old woman on the fifth day, seeing the child so easy under a fracture of the femur, shrewdly suspected that the bone was not broken at all, and that the surgeon was only "making a job of it." She whispered her suspicions to another old crony (the child had lost its mother), and these wretches took off the bandage, and actually placed the child upon its feet! The bone of course was displaced. The mischief was done, and felt the crepitus, the child screamed, and, conscience-stricken, the old women Gaye was sent for, who, without delay, age, and, *secundum artem*, splinted it, and the pieces of veneer, though with more

pressure than is consistent with any mode of procedure. The child ultimately did well; and so, indeed, do others, even where much unnecessary force is employed. Mr. Gaye, my esteemed friend, makes very good cures indeed, and uses splints; but he is extremely careful, and does not employ a title of that force which I have seen employed. Still, I repeat, that all splints are useless. Pardon me for saying as much for about the twentieth time; but I should continue to say so to the twenty thousandth time, to banish splints from surgery.

CASE 5.—Richard Curnell, aged 45 I think, a pauper in the village of Kingsteignton, in the month of August 1831, slid from the top of a large corn rick which he was thatching, and fell to the ground. The height was upwards of twenty feet. The clavicle and the femoral shaft on the right side were both fractured. The fractures were not compound, but the depth of his fall and the violence of the shock greatly aggravated the symptoms. The thigh was placed on a long pillow, on a bed perfectly soft, and treated with the tailed bandage, wetted with cold lotions; the skin was sponged with tepid water several times a day, allowed freely to evaporate in the common atmosphere of his room. As the cure advanced, camphorated and oily embrocations were applied generally over the limbs, and, at last, the supporting circular plaster of leather, overlapping the fractured portion, kept on with a bandage, perfected the cure.

The progress of this case was as satisfactory as an ill-fortune so severe could be; for the patient's sufferings were obviated by simple management, and fortunately for him he was a member of a "Sick and Hurt Club," so he did not hurry himself in getting about too soon, like some poor fellows must do. One circumstance occurred in the progress of the cure which pleased me. The clergyman of the parish, the Rev. T. W., in his accustomed visits to his sick parishioners, expressed surprise "that splints were not applied to Richard's thigh;" but when he found that it was not a part of my plan to apply splints, he politely acquiesced, and ceased to advocate their use; for which I thank the reverend gentleman,—for many reasons, one of which is, because the feelings of the poor are most easily excited against their medical attendants on matters which have even only the appearance of rationality to justify complaints, which in such cases as these might be thought well justified, when such men as Mr. Pott, to use his own words, declare, "that without splints the cure would be a vain endeavour to maintain the position of fractured bones;" and the medical writer, with more reason, I suppose, assures us, that "of different pieces of the apparatus for the treatment of fractures, the splints are by

far the most important and essential. Without them, indeed, it would be in vain to attempt to keep the extremities of the fracture from being displaced." Once more I repeat, that I have never found cause to attempt to keep the fractured ends of bones together by splints and tight bandages. The bones stay in their places, and maintain good and proper positions, without giving me the unnecessary trouble of making the attempt. And why? Because I have never, by irritating causes, given the muscles reason to be angry with my treatment, and, as an expression of their resentment, to "displace" the bones, and give me the trouble and the patient the pain of again reducing them.

Two cases of dreadful compound fractures, terminating fatally, were hinted at in a former part of this paper. A man named William Tickle was standing between two pieces of granite, one of which, about a ton weight, fell edgewise against his leg, and crushed the bones against the flat side of the opposite stone. The state of his health and strength would not warrant amputation, and he died of mortification, extending through the body, on the ninth day. Mr. Gervis of Ashburton saw him, but nothing more could be done to save him.

The other case was that of the man named George Cole, who, in the month of December 1826, had both legs dreadfully shattered by a premature explosion of gunpowder placed in a horizontal hole in a mass of granite. Mr. Gervis saw him with me, and I determined to take him to the *Exeter Hospital*, with the concurrence of Mr. Gervis. He was removed thither in a spring car upon a feather bed. He bore the journey well, suffered amputation of both legs on the following day, and died two days afterwards. These are the only fatal cases of fracture that have occurred in my practice, and fatal they would have been anywhere. But there are very many of my patients whose present habitations and mine are, by the hand of fortune or of death, far separated,—who could have borne most ample testimony that their fractures were cured by the means which I have described in these papers. My next case is one of great importance in the history of the mode of cure now insisted on.

CASE 6.—George Wills, aged 30, living with Mr. Bowden at Well Farm, in the parish of Ideford, on the 22nd of January 1831, coming home on a dark night, overturned a heavy cart, the rail of which falling across his leg, fractured both the tibia and the fibula. He had, some three or four years before, broken his other leg, by jumping out of a cart. And now for the contrast in the treatment on the two occasions. In the first accident the limb was splinted up most carefully—so carefully that he was kept in

bed, for seven weeks, and a considerable time afterwards elapsed before he was able to work. On this occasion it was my turn to assist him. The fracture of the tibia was as oblique as it could be, the superior portion overlapping the inferior, and the point of the obtruding end above, having nearly penetrated through the skin at the small part of the leg. He was now placed in bed with his leg on a pillow, in the way which I have already sufficiently described, and, leaning on his elbow, he watched proceedings with much attention.

"Which way do you most usually lie in bed?" I asked. "Do you prefer lying on your back or your side?" "On my right side." "Very well," said I. He was then reclining on that side, it was his right leg that was fractured, so he remained in the same position. The leg was first gently extended with genuflexion, and the thigh a little raised towards the pelvis. A very slow and reiterated course of extensions was then made, until the contour of the limb pleased me; the tailed bandage was next laid on, and then the pillow was tied up, padding it to a regular bearing on every part, and until the patient said, on being asked, that it lay easy in every respect—not harder at one point than another. The following dialogue then followed:—

Wills (reclining, half raised on his elbow).—"Why, Doctor, don't you put splints on my leg?"

R.—"Because, my friend, I always cure broken bones without them."

Wills.—"Humph! Well, to be sure, Zir, you ought to know best about it; but when I broke my leg last time, that Doctor splinted it up well all the time I was in bed."

R.—"And for how long a time was that?"

Wills.—"Why, rather more than seven weeks in my bed and room, and the splints were kept on afterwards too."

R.—"Were the splints applied tight or not?"

Wills.—"Tight, I faith! ah tight zure enough!"

R.—"How did your leg feel? Was it not very hot and painful at times?"

Wills.—"Iz, I faith! 'Twas painzure enough, it beated and clapped like one's pulse again (agoing), and I couldnt sleep nor be azy, all day and night long, for a good while, and I ax'd the Doctor about et, but he told ma I must bear it, bekaze the bone couldnt be cured without et."

R.—"Well, no doubt what you say is true enough, I don't in the least doubt its truth; but don't you fear: I shall, in four weeks, make as good a cure of your leg as the other was in seven weeks, and you shall not suffer this time."

Wills lay back in bed and shook his head, but answered nothing. His looks expressed his doubts without any necessity for speech. I saw him three or four times that week, as

it was only four miles from Newton. The limb during the interim was frequently bathed with warm water and lotions,—first of *Plumb. Superacet. et Aqua*; next—*R. Pulv. tassa Nitrat. ʒi solve in Aqua liij. Tr. Opii, et Myrrhae, aa. ʒss. Add.* The bruise from the cart rail on the stones was severe, and he took *Extr. Belladonnae gr. ij ad gr. vj* on noct. with composing effects. On the seventh day *Lint. Saponis Comp.* was used to moisten the sore and tender surface of the leg. Lotion for the bandage as before.

On the second week I saw him but twice, and on visiting him on the nineteenth day from the accident, never had I felt more surprise in such a case. I found my patient delighting himself at my expressions of surprise, with his leg resting on a pillow upon the long seat in the kitchen. I warned him, with some feeling, of the danger of coming down-stairs, thinking it premature, being a fracture of both bones, and one bone in this case could not become a support to the other—always better than a splint, if you please. But on looking at his leg I found that no limb could present a more fair and equable surface. He was a young and healthy man, yet the short time occupied in the remedial process surprised me. Union had taken place, though not firmly. While cogitating over it, the jocose fellow threw the flexor and extensor muscles of his leg into strong action, which made his leg bend at the fractured part like an osier twig. I felt the blood rush into my face, and exclaimed—"If your leg is so well, don't play the fool with it." "Why, Zir," said he, "tis no pain to me." "No, I don't suppose it is," said I, "but 'tis the right way to do mischief."

A medical man is all his life a student. Every case presents some new claim to his notice. Talk of displacing bones when once fairly reduced! Why, 'tis the surgeon's fault or the patient's, certainly not the fault of nature in her interrupted operations. The man did not displace the bones at all, and I was not slow in passing a circular overlapping plaster around the united parts, on my next visit, with a warm and comfortable bandage, the month being February,—the depth of winter. Words can faintly tell how delighted and thankful he was at this, to him, surprising cure. To be cured without pain was unaccountable to him, and he was endless in his contrasts between the two methods. No man could be better pleased, and he was, with additional good reasons, pleased, when he compared my charge with his former long bill.

On the 25th of February, more than five weeks from the accident, I called and re-
had been out of doors
superintending his man
and paid me off with thanks.

CASE 6.—Mr. Bowden, the master, fractured his fibula, in the following Christmas, also dislocating his ankle. He lay in bed but a month, and then recovered. He could not bear a plaster around the part, but got well without it.

CASE 7.—An old Newfoundland man, residing in Kingshenwell village, presented a somewhat parallel case. Twenty years before, and it had been my turn to serve him; he had broken his leg while engaged in the Newfoundland fishery. One night in the Christmas season of foolish carousing, he fell down on his road home, in the dark and dubious way, and again broke the same unlucky leg. This might be called act the second. His leg was treated with the same routine as my other cases, though with very humble materials. He returned to his work at the end of four weeks, and many a sailor-like oath did he bestow on "the blockhead of a doctor" who had kept him "so long belayed in board splints and blankets, in his berth, on board the old brig, on the banks of Newfoundland."

CASE 8.—Another case, which occurred the Christmas before, was that of a man 50 years of age, who had lived freely. Walking over a wooden bridge on a frosty night, his heels slid away, and he fell backwards, and the elbow of one arm received the violent shock of his descent. He was a very heavy man, and the injury was correspondingly severe. Being at a distance of four or five miles, they did not send for me until the next morning, when I found the arm much swollen. The humerus was fractured obliquely, passing into the elbow-joint, and the inferior portion of the bone projected anteriorly, where the biceps muscles become tendinous, and the bone just pointed through the integuments, and made it a work of time and tact to reduce it, as the bone stuck in the tendinous expansion. Here was a compound fracture, with complications enough, and a bloated constitution to boot. Did I place this dreadfully injured arm in a splint? Would any other surgeon have laid it on a splint of any sort? Let the practice of Sir Astley Cooper and his colleagues answer,—a practice recommended by lofty-minded men, in elevated stations in society, with all the force and influence of splendid folios. This man employed all the little resources which I could suggest to reduce the alarmingly increased action of the arm and forearm. Many would have recommended amputation at first, but he escaped that, and gangrene also, and in five weeks left his bed. I then bring a fork or a cup to his mouth.

On the 20th of August last, Mr. [Name] of this town, while driving a bill, had the harness [Name] broke, which severely lacerated the [Name] and thicker portion of the tibia,

which was broken obliquely, transversely, four or five inches below the lower edge of the patella. The fracture was one of "the worst" species of simple fracture, as it is termed, the iron points or talons of the horse's shoe inflicting two wounds at the line of fracture, one of them deep and lacerated. There was much tumefaction in two hours afterwards, when I was called in. Truth compels me to say that a practitioner had examined the injury before I saw the patient, but a sudden obstetric call made him leave in a hurry, and the splints were left behind also. I reduced the ends of the bone, and bandaged and laid the leg on a pillow, in my old way. The pair of neatly-turned hollowed-out splints lay on the chest of drawers, and there they remained. "No," said I, as they lay there to tempt a surgeon to use them, "you are for ever banished from my hands. No more the galling splint for me; no more!"

Mr. Leslie, who usually attends this family, entered at the latter part of the bandaging-up, and, with true politeness, did not alter the state of things. It always gives me pleasure to record such instances of urbanity. The patient did well up to three weeks' end. Mrs. Russell was a very clever nurse, and bathed, and managed well the wetting system, turning the bandage off and on many times in the twenty-four hours. I am delighted to attend on these cases; they are worth a man's efforts and energies to relieve them. Mr. Leslie being away, I saw Mr. Russell every day, until Mr. Leslie returned, and splinting up the leg, took him out of bed. This was on the eighteenth day from the accident. Union had well advanced, the cure was so far complete, and the patient's impatience would not allow him to remain longer a-bed. The splints were long, and well-padded, and as no particular soreness remained, they did no harm,—nor good, excepting that the patient's mind was assured that they would be "a safeguard against accidents." But their appearance is to me always awkward and grotesque in the extreme. Mr. Russell went down-stairs in a few days afterwards, and on Tuesday the 22nd of September, two days less than five weeks from the accident, he stood on the grassy plain of Denbury Fair, viewing the horses, and soon wholly recovered, by the aid of the wide circular overlapping plaster and bandage, he having previously laid aside the splints.

CASE 10.—The last case, and to me and my patient not the least gratifying, I shall mention, may now be examined by all those who feel concerned in such misfortunes. Cherry Tracey, aged 40, the mother of ten children, on Wednesday, the "glorious" 21st of October last, was gathering acorns, when, while holding fast by a small branch with one hand, and picking

bed, for seven weeks, and a considerable time afterwards elapsed before he was able to work. On this occasion it was my turn to assist him. The fracture of the tibia was as oblique as it could be, the superior portion overlapping the inferior, and the point of the obtruding end above, having nearly penetrated through the skin at the small part of the leg. He was now placed in bed with his leg on a pillow, in the way which I have already sufficiently described, and, leaning on his elbow, he watched proceedings with much attention.

"Which way do you most usually lie in bed?" I asked. "Do you prefer lying on your back or your side?" "On my right side." "Very well," said I. He was then reclining on that side, it was his right leg that was fractured, so he remained in the same position. The leg was first gently extended with genuflexion, and the thigh a little raised towards the pelvis. A very slow and reiterated course of extensions was then made, until the contour of the limb pleased me; the tailed bandage was next laid on, and then the pillow was tied up, padding it to a regular bearing on every part, and until the patient said, on being asked, that it lay easy in every respect—not harder at one point than another. The following dialogue then followed:—

Wills reclining, half raised on his elbow.—"Why, Doctor, don't you put splints on my leg?"

R.—"Because, my friend, I always cure broken bones without them."

Wills.—"Humph! Well, to be sure, Zir, you ought to know best about it; but when I broke my leg last time, that Doctor splinted it up well all the time I was in bed."

R.—"And for how long a time was that?"

Wills.—"Why, rather more than seven weeks in my bed and room, and the splints were kept on afterwards too."

R.—"Were the splints applied tight or not?"

Wills.—"Tight, I faith! ah tight zure enough!"

R.—"How did your leg feel? Was it not very hot and painful at times?"

Wills.—"Iz, I faith! 'Twas painzure enough, it beated and clapped like one's pulse again (agoing), and I cou'dnt sleep nor be azy, all day and night long, for a good while, and I ax'd the Doctor about et, but he told ma I must bear it, bekaze the bone cou'dnt be cured without et."

R.—"Well, no doubt what you say is true enough, I don't in the least doubt its truth; but don't you fear: I shall, in four weeks, make as good a cure of your leg as the other was in seven weeks, and you shall not suffer this time."

Wills lay back in bed and shook his head, but answered nothing. His looks expressed his doubts without any necessity for speech. I saw him three or four times that week, as

it was only four miles from Newton. The limb during the interim was frequently bathed with warm water and lotions,—first, of *Plumb. Superacut. et diluta*; next—*R. Pulveris Nitratis* ʒi solve in *Aqua* ℥iij. *Tr. Opii*, et *Myrrhe*, an. ʒss. Add. The bruise from the cart rail on the stones was severe, and he took *Ext. Belladonnæ* gr. ij ad gr. vj om. noct. with composing effects. On the seventh day *Lint. Saponis Comp.* was used to moisten the sore and tender surface of the leg. Lotion for the bandage as before.

On the second week I saw him but twice, and on visiting him on the nineteenth day from the accident, never had I felt more surprise in such a case. I found my patient delighting himself at my expressions of surprise, with his leg resting on a pillow upon the long seat in the kitchen. I warned him, with some feeling, of the danger of coming down-stairs, thinking it premature, being a fracture of both bones, and one bone in this case could not become a support to the other—always better than a splint, if you please. But on looking at his leg I found that no limb could present a more fair and equable surface. He was a young and healthy man, yet the short time occupied in the remedial process surprised me. Union had taken place, though not firmly. While cogitating over it, the jocose fellow threw the flexor and extensor muscles of his leg into strong action, which made his leg bend at the fractured part like an oster twig. I felt the blood rush into my face, and exclaimed—"If your leg is so well, don't play the fool with it." "Why, Zir," said he, "tis no pain to me." "No, I don't suppose it is," said I, "but 'tis the right way to do mischief."

A medical man is all his life a student. Every case presents some new claim to his notice. Talk of displacing bones when once fairly reduced! Why, 'tis the surgeon's fault or the patient's, certainly not the fault of nature in her uninterupted operations. The man did not displace the bones at all, and I was not slow in passing a circular overlapping plaster around the united parts, on my next visit, with a warm and comfortable bandage, the month being February,—the depth of winter. Words can faintly tell how delighted and thankful he was at this, to him, surprising cure. To be cured without pain was unaccountable to him, and he was endless in his contrasts between the two methods. No man could be better pleased, and he was, with additional good reasons, pleased, when he compared my charge with his former long bill.

On the 25th of February, more than five weeks from the accident, I called and renewed my charge, and had been out of doors superintending his man, and paid me off with thanks.

CASE 6.—Mr. Bowden, the master, fractured his fibula in the following Christmas, also dislocating his ankle. He lay in bed but a month, and then recovered. He could not bear a plaster around the part, but got well without it.

CASE 7.—An old Newfoundland man, residing in Kingsheavenwell village, presented a somewhat parallel case. Twenty years before, and it had been my turn to serve him; he had broken his leg while engaged in the Newfoundland fishery. CASE 10.—The last case, and to me and my patient not the least gratifying, I shall mention, may now be examined by all those who feel concerned in such misfortunes. Cherry Tracey, aged 40, the mother of ten children, on Wednesday, the "glorious" 21st of October last, was gathering acorns, when, while holding fast by a small branch with one hand, and picking

with the other, the twig broke, and she fell with force enough to fracture the tibia transversely. This was a mild case of the sort. I saw it nine hours after the accident, and applied the wetted bandage over the leg. The fracture was one inch only below the centre of the bone. A pillow was too high for her leg, because she sank down so low in the bed; a little hollow was therefore nestled out for her leg in the bed itself, and therein the limb was padded up, on a good plane. She began to do well at once, and on the Saturday week after, in the evening, ten days from the accident, on calling to see her, and asking her when she thought she would like to get out of bed, she replied with timidity, "Ha, sir, I have been out a little to-day." She actually had been out for three or four hours. I cautioned her to beware, but she regularly arose in the morning, and remained out the whole of the day every day afterwards. A plaster was applied around the leg, in the usual way, with a bandage, by which means, in her two rooms on the same floor, she manages, with crutches, to perform her family affairs for a husband and several children. All this was done spontaneously, before I was aware of the full extent of her recovery. Indeed, the reader may have observed, that nature has often outrun my expectations in the progress of her work. I have assiduously watched the progress of this case, taking care to hammer in a rough nail in the end of each of her crutches, lest some slip should produce an unlucky fall, and mar this almost wonderful and truly surprising cure. I believe the quickest union before recorded is one of twelve days, in a child, but this exceeds it in rapidity; but as to the *degree* no one can speak. A woman who has passed the prime of her days, having had a large family, enduring privations as a pauper, was here able in some degree to rest her foot on the ground, in ten days after the occurrence of the fracture! Let the doubters of splintless cures hear this. Will they still assert the indispensable necessity of using splints? At the end of my present argument had I desired a case to form a climax, what fact could be more appropriate than that which I have just stated? Let the case be examined by any person. Let the rev. gentleman of Kingsteignton institute a personal scrutiny into the facts which it presents, and then let me have a fair meed of praise for introducing and advocating a mode of cure so benign in its influences. More than this I do not wish; with less I will not be satisfied.

In conclusion, let me address a few words to the young student, whose mind is ardently engaged in a search after truth, and who has time and patience to consider the facts of a case. I will, in fancy, place myself in a dissecting-room, and imagine the shade of Brookes,—would that he could in body still

be here,—to descant on some such anatomical and physiological subjects as the following:—

Every rib except the first and the last is wedged between its neighbour ribs. Gravely the rib is shielded superiorly, and supported below by its fellow rib, the first and last excepted. In a fracture of these bones, each of its fellows forms a natural support to it. You cannot apply a splint here, and if you could, the natural allies of each rib would form a better support than any artificial aid.

The radius and ulna sympathize with and support each other, in the misfortune of fracture happening to either; while, with one point of exception, from peculiarity of structure and office, the interosseous muscle and ligaments keep them in close contact, and they cannot therefore require the aid of splints. If both these bones at once are broken, be assured it will be quite natural for them, like the Siamese youths, to lie still together, unless you molest and "bind them fast in fate," in the painful fate of splints.

Is the humerus or the femur broken? The latter, in particular, is invested all around, and beautifully and strongly inclosed within, by integuments,—by an unyielding fascia made tense at the pleasure of the will, supported by a mass of muscles, its natural defenders; with a host of vessels to supply it with warmth and to afford the means of restoring its continuity, a continuity not lost, but merely interrupted; nerves, also, exquisitely alive to pain, which warn of the approach of danger, and will not impel their obsequious servants, the muscles, to disturb the bone, unless offended by irritating causes; and if through force or violence the bone is impelled through the investing coverings, reduce it to its place *in situ*, and all will be well, if you withhold interference with the operations of nature,—an interference that will be prejudicial, though honest.

In a fracture of the fibula we need not trouble ourselves with splinting, because its tried friend tibia will, with rest, compel it to keep its own place better than any external aid. Again, is the tibia itself broken? The interosseous ligament, when not ruptured, is a firm band of union between the two bones, just commensurate with their length. We may further quote the words of a good surgical authority:—"The fibula resists the causes that tend to produce displacement of the tibia, when fractured." Thus much for the support given by bones in juxtaposition.

But should both these bones be broken, do not fear they will be too weak to sustain a condition to sustain the limb in such a state as fits a man who has received a stunning knock. He cannot rise again, until there is a

recovery of sensation. So the leg, if not irritated, will have a disposition to lie still until well recovered. Assist the cure, and when once settled, be careful not to inflict pain on it.

Reverse all this. Apply the splints. First you will irritate, and then forcibly repress the influence of a most sensitive nervous surface, compressing arteries, veins, and absorbents, and then combatting the ill effects until you conquer and subdue their friendly resistances to your vile force, ultimately bringing some portions of the soft parts into painful collision with the fractured ends, to be grated between their sharp margins,—to be jagged by the teeth-like fragments of the broken bone.

If a surgeon who is also an *anatomist*, after pondering over these cases and arguments, still continues to apply splints to fractures, should not he —

But the language of sarcasm is not my *forte*, nor do I wish to use it, save by way of useful aid to mild arguments. Yet the importance of lessening human suffering, warrants the use of every means of rhetorical force. Let it not for a moment be thought, that in describing the ill effects of coercion and undue restraint under the employment of splints, I have at any time used the language of hyperbole. No; the superfluous misery endured in the slow and painful course of past ages, under the splinting system, can never be exaggerated in description. What a huge mass of human suffering has arisen from the unnecessary inflictions of pain by splints alone! I do not rashly speak when I assert that full one-half of the misery which has been endured in fractures, has arisen from the long-continued use of splints, or, in other words, what pain has been heaped upon us in these cases by maltreatment alone! But shall we still persevere in this course? Shall we still go on rolling up the Pelion of our powerful but foolish exertions to load the *Ossa* of unavoidable calamity? Forbid it, Heaven! Unavoidable misery is a mountain huge enough in itself to press us to the dust, without the weight of extraneous and gratuitous evil.

But granting all I have advanced to be strictly true; if, instead of myself, who occupy a private station, some one of those men who stand the highest in our profession, had first proved the truth and value of the splintless system, and then had sounded forth the great improvement to the world, with how much greater celerity would the change advance, and how much more worthy of public adoption and of confidence should it be considered!

Moreover, it has been introduced with the mediocrity of talent which is not that the facts and rules stated will, ere long, be upheld by some man of high standing in society, who

shall clothe my system in the glowing language of science, and in a style which will charm the world to a belief of its truth. For though I myself well know that in all cases of fracture, my mode of cure is to the patient the safest and the best, and, beyond dispute, cannot be surpassed in the simplicity of its operation; yet slow is the progress of first improvements! But I am well convinced that surgical art will not have reached the acme of perfection, without some such simple plan of treatment as I have endeavoured to press on the consideration of my professional brethren, being first adopted. Yet an age may pass away before this mode of cure, waging war as it does with a multiplicity of interests and prejudices, shall conquer and prevail. Before I shall have aroused the attention of the careless, made converts of the rich, persuaded the proud, convinced the opinionated, and compelled the interested and the obstinate to yield to the influence of shame, many years may have rolled away. Thrown then, as it is, gratuitously on the professional public, I hope that the public will give a fair trial to the system of cure, and pass a fairly considered verdict on that which I design to confer benefit on thousands of suffering individuals.

Nov. 10th, 1835.

REFLECTIONS

UPON

INFANTILE REMITTENT FEVER.

By JOHN ALEXANDER, M.D., Physician to the Infirmary for the Diseases of Children, Manchester.

(Continued from page 419, No. 617.)

“WHATEVER splendour,” remarks an experienced writer, “the actual *treatment* of diseases may reflect on the science of medicine, it by no means comprehends the whole of its province; for *prevention* being in every case preferable to *remedies*, the medical art would be more imperfect than other science were it devoted only to the latter.”

Let us then (with a view to prevention) briefly allude to those circumstances which favour the origin of infantile remittent fever. They are of varied character. The neglected inhabitant of the damp cellar and the petted lordling of the luxurious nursery—the half-fed child and the highly pampered offspring, are alike prone to an attack; the latter from the absorbent system being encumbered with a load of nutriment which but too often requires a fever to admit of its removal, and the former from defective nutrition, developing a morbid action which is observed to be equally excited by deficient or by superabundant support. Hence it results that a child threatened with

the malady under consideration, must be regarded relatively to the ascertained nature of those mal-influences to which it may have been subjected. The overfed should be put upon a light unirritating and somewhat scanty diet; whilst the debilitated and exsanguineous must, if possible, be more warmly clothed, removed to drier air, and have better support. Unhappily, the last important desideratum is one which every medical attendant upon a dispensary must have experienced, as being easier prescribed than put in force, and hence it constitutes one great cause of the frequency and obstinacy of infantile remittent fever in the lower walks of society. If, however, we succeed in banishing all fresh vegetable and salted food from the dietary of the pauper child, and substituting milk, bread, and rice, in their place, a great point will be gained; as the staple diet of the poor, viz., potatoes, contributes no little, in the estimation of the present writer, to the disorder's aggression. The observed circumstance that infantile remittent never attacks children at the breast, when the mother's health is good, speaks, I think, volumes as to the influence of food in originating the malady. In both the plethoric and debilitated, a course of alterative aperient medicine is not merely proper, as indicated by the character of the abdominal secretions and appearance of the tongue, but frequently proves effectual in warding off a strongly-threatened attack of the malady. To those families whose younger branches have been liable to febrile affections, an annual visit to the sea-side has always appeared to me highly beneficial: nor are airiness of the sleeping apartments, the constant use, in clothing, of flannel, and regular daily exercise, to be overlooked with impunity.

Provided we were servilely to adopt the pathological views of our continental neighbours, without judging for ourselves, we should refer the cause or nature of infantile remittent fever almost exclusively to inflammation of the digestive mucous surfaces. On autopsy this status or condition is doubtless often observed: but practitioners in this country do not draw their conclusions from limited data, on the isolated and deceptive evidence of mere morbid anatomy; although, I fear, it cannot be denied that, even with us, an undue attention is arising to the latter, which will prove eventually injurious to symptomatology and therapeutics, the really practical part of the Hippocratic art. This creed is not the popular, and I hope may be a mistaken, one.

But, to return.—The majority of cases of infantile fever the present writer has witnessed, have afforded little evidence of inflammation being its cause; neither does the infinitely more important evidence of HOFFMAN, FEMBERTON, and BRETHER, sanction the idea. Moreover, Dr. COPLAND, in an

admirable digest of the views of others, vide "Cyclopædia" and remarks most conclusively as follows:—"That infantile remittent fever does not consist of inflammation, is shown by the character of its early symptoms, by its course, termination, and consequences, and by the juvenia and ladentia"—"a strumous diathesis, a morbid state of the abdominal secretions, an obstructed condition of the mesenteric glands, particular disturbance of the liver, or a debilitated nervous system, may, it is possible, give rise to this disorder by their single mal-operation in individual cases; but their conjoint influence I apprehend should be referred to, as constituting the usual origin of the complaint. Diseases are not, either in their sources or their symptoms, regulated by the definitions of nosologists; and, probably, that medical philosophy is not the most illogical which admits of a varied and mixed causation as well as of varied effects!"

Infantile remittent fever making its aggression under varied forms,—sometimes with symptoms of mere disturbance of the first passages; sometimes under the slow and insidious form of marasmus, unattended with much vascular excitement; and sometimes with many of the tumultuous phenomena attendant upon inflammatory fever,—I have in practice found it necessary to adopt a treatment modified accordingly. When the disease commences with loaded tongue, nausea, chills, oppression at the precordia, constipated bowels, and high-coloured urine, emetics are of signal service by relieving the oppressed first passages, diminishing the fever, and cutting short the complaint's duration. Indeed, their use, continued for a few mornings, accompanied by general aperients, and succeeded by strict attention to suitable diet, often suffices in a very short time to restore the little invalid to health, which in some slight cases may have appeared, to the superficial observer, to have been little threatened. On close attention, however, the characteristic evening febricula is easily recognised, and secures the necessary attention.

The most incurable variety of the disorder under consideration assuredly is the one characterized by the apyrexial and marasmic conditions; doubtless from these two circumstances,—the complaint having in too many cases made progress before professional relief is sought, and from an originally weak or specifically affected state of the child's constitution. In a large proportion of these cases, particularly amongst the poor, whose damp habitations and improper diet counteract our remedial designs, little can be done. In a few apparent instances, however, warm bath, and perseveringatives (carried to gentle degrees), succeeded by light tonics, have proved good. Nor has the occasional

of a mild blister over the region of the liver been unattended with benefit. Many practitioners entertain a very high opinion of rubefacient liniments to the spine, and over the abdomen. There is no objection to their use, as this form of infantile remittent is unaccompanied by irritability; but I may add, after an extensive trial of them, that the present writer has not been able to realize the benefits others seem to have derived from their employment. The following case will illustrate the disorder's obstinacy, and inculcate a cautious prognosis:—

In the month of May last, the child of a Mr. D., of Rochdale, *ætat.* fourteen months, was brought to Manchester for my opinion. It had been under the care of two highly respectable and intelligent practitioners of that town, who had adopted for a considerable time every variety of treatment they could think of. The child's case was, though by no means an uncommon, an admirably marked example of chronic infantile remittent fever. Upon the closest scrutiny, no evidence of organic disease could be detected; little pyrexia accompanied the complaint's progress, and the child took everything, whether in the form of food or medicine, that was given to it; yet I am not aware that the slightest benefit followed the use of those additional remedies which were for some time employed by the present writer. Indeed, according to my general experience, if the means alluded to before, *viz.* very warm clothing, the hot-bath, mercurial alternatives, &c. fail, after a fair trial, little benefit will accrue from a further use of medicine in this unpromising state of atrophy. Change of air, a generous diet, and cordials, may be tried, and in some rare instances they unexpectedly effect our object.

When infantile remittent fever assails plethoric children, previously in tolerable health, it is generally observed under the last alluded to, or tonic form. For this variety energetic measures are required, and their use seldom disappoints us. After the prima via has been well cleared (of which the practitioner should have ocular daily proof), by the persevering use of purgatives, such as *scenna*, *cabulic*, *jalap*, *scammony*, &c. and the accumulations so often observed in this complaint, are removed, it is not unusual to find the child complaining of pain in some one of the abdominal regions. Its seat is very various. A few leeches, warm fomentations, and a succeeding vesication, or the antimonial ointment, seldom fail in its removal. After promising these measures, it has been customary with me to recommend the employment of a mercurial (say, *c. creta*), combined with small doses, of which latter the medicinal affections of the system, and we can scarcely entertain a high opinion. Every one who

has seen much of infantile remittent fever, will acknowledge *irritability* to be one of its most prominent features. On this account the addition of a little opium to the evening mercurial, in most cases is accompanied with benefit, with this proviso, that the tongue is disposed to be moist before we employ it. Occasionally however, as with the adult, opium disagrees, and hyoscyamus affords a good substitute. Enemata, throughout the whole of this malady, are most appropriate remedies—varied of course according to age, temperament, and other attending circumstances. As one almost invariable ingredient therein, spirits of turpentine will be found useful, as in a large proportion of instances of the malady, the fever is heightened and the irritation increased by the presence of worms. As soon as the pyrexial symptoms have declined, and not before, calumba, iodine, and cascarrilla, may be employed, in forms as suitable to a child's palate as possible, intermitting not, however, the morning use of some gentle aperient, which, during the whole course of the disease (a period averaging probably three weeks), must be regularly enforced. Wine may now be found a useful auxiliary.

In conclusion, let me remark that the junior practitioner must not be surprised at the occasional failure of his best-laid and most promising measures. The fretfulness of the little sufferer, the perversity of ignorant nurses, the occasional impossibility of administering remedies by the mouth, and the natural obstinacy and dangerous character of the disease, will, sometimes, but too successfully, combine to thwart and disappoint his wishes.

Manchester, Nov. 11, 1835.

HEMORRHOID IN THE RECTUM,

FOLLOWED BY

ABSCCESS IN THE PERINEUM,

WITH FISTULA RECTI ETC.

To the Editor of THE LANCET.

SIR.—As the following case will, perhaps, be considered to possess some practical interest, I shall feel obliged by its insertion in the pages of your journal. I am, Sir, your obedient servant,

ROBT. ROMLEY CHEYNE.

57, Berners-street, Nov. 11, 1835.

Mrs. K., *ætat.* 50, of a sallow complexion and spare figure, housekeeper to one of the West-end Club-houses, consulted me on the 22nd of last August, for what she called very uneasy sensations, with extreme weakness, about the loins and hips, and severe pain in the calves of her legs, increased by

walking, or any exertion. She had thus suffered during two months, and knew no cause for her complaint. The menstrual secretion ceased six years ago, since which time, until lately, she had been perfectly well. She had never, to her knowledge, had piles, nor passed blood by stool. The bowels acted regularly, and without pain. She had never had leucorrhœa; her constitutional symptoms, when I first saw her, were not severe, the pulse being very little quicker than natural, the tongue only slightly furred, and the skin cool and moist. She experienced, however, much anxiety (which was expressed in her countenance), from the apprehension of permanently impaired health.

This history, I must confess, induced me to consider the case as one of sciatica, and (acting on that idea) to recommend very moderate diet, gentle aperients, thirty minims of *Vin. Colchici* in *Mist. Camphoræ*, three times a day, and the use of the warm hip-bath every night at bed-time.

This and similar treatment, continued until the 26th, afforded partial relief, but still there existed a sensation of weakness, and, lately, of soreness, about the hips and perineum; and once, when at stool, a slight pain had been felt shooting through the anus. From these facts I now hoped to obtain light enough to dispel the obscurity of the case. As I was aware that diseases connected with the rectum often assumed very anomalous characters, an examination *per anum*, was immediately proposed, with the view of ascertaining whether the present was a case of that nature. The result was, the detection, about an inch within the anus, on the floor of the rectum, of the presence of a soft elastic hemorrhoid, of the size of a cherry, surrounded by some thickening and swelling, as if the coats of the bowel were pushed inwards by fluid in the vicinity. The impression, too, of distinct fluctuation, was given to the finger, when forcible pressure (which gave no pain to the patient) was made by the other hand, on the perineum. All doubt being now cleared away, the proper practice was evident. The contents of the abscess should have been at once discharged through a large opening, and then, in all probability, my patient would have been well in a few days; nothing, however, would induce her to consent to my request: she could not imagine the existence of an abscess without much more pain than she experienced. Under these circumstances nothing more could be done than to advise her to keep quite quiet, to take a teaspoonful of *Elect. Senna* every night, and to inject an enema of warm water every morning.

Thus the case proceeded until the 1st of September, when I was hastily summoned to my patient, whom I found suffering acute pain in the perineum, the integuments of

which were now of a livid red colour, hot, and swollen, and acutely tender on pressure. There was, also, as might be expected, a great deal of symptomatic fever. The application of twenty-four leeches was immediately ordered, and afterwards a warm poultice; and in the evening these measures were repeated, and an anodyne draught was administered.

The next day the pain and swelling were less; but there was more fever, and some difficulty in making water. No further opposition being now offered, a free opening was made near the anus, when more than half a pint of dark-coloured offensive pus, with bubbles of gas, escaped, to the surprise of the attendants, and with great alleviation of the severe pain and feelings of tension in the part. A poultice was then applied, and directed to be repeated three times a day, and an anodyne to be taken at bed-time.

Sept. 3. Has had a restless night; pulse 120; tongue loaded with a brown fur; copious discharge, mixed with sloughs of cellular and adipose tissues. Complaints still of much soreness and distention about the perineum; to relieve which, another opening was made, and a great quantity of pus flowed out.

R *Ammôn. Salsæ* ℥. gr. xvj; *Acid. Tartariz.* ℥ij; *Aq. Distil.* ℥ss. M. et int. effervescentium 6ta quaq. hora sumatur. Contin. catap. et haust. anod.

4. Has had a better night; looks less anxious; pulse 110; bowels open; no difficulty in making water; copious discharge, and the sloughing continues. Cont. medic. et catap.

7. Has been improving for the last three days. Sloughing has nearly stopped; no pain; less fur. Cont. medic. et catap.

The three weeks following the last report were spent in aiding the efforts of nature to repair the extensive mischief, which, as has been seen, was the work of only a few days. During this time the sloughing process had converted the incisions of the lancet into a deep cavity surrounding the intestine, laterally and posteriorly, discharging at first an unhealthy pus, which, however, improved in quality, in proportion as the constitutional vigour of the patient was restored under the use of tonics and good diet. Strong astringent lotions were also employed, of which those composed of *Sol. Chlor. Calcis*, and port wine and water, seemed the most effective. The stage of granulation at length commenced at the bottom of the abscess, and continuing all, save a fistulous canal, healed up, which, when traced was found to communicate in three places - viz. one, two from the anus; another, through

of the hemorrhoid above alluded to, and the third close to the base of the latter.

As it was now evidently useless to waste time in the effort to cure the fistula without the operation, this was performed,—the incision dividing all the parts included between the highest opening into the intestine and the anus. After this the granulating process recommenced, and went on until it reached the situation of the two other points of communication with the rectum; and now, instead of again using the knife (as the hemorrhoid could be readily drawn out with a hook), a ligature was tied round its base, including that portion of the mucous membrane in which the third small aperture could be distinctly seen. In three days the ligature came away during the action of the bowels, and from that period the case proceeded so well, that towards the close of the month Mrs. K. went into the country quite recovered, promising, however, to continue the use of an enema of warm water twice a week for some time, in order to ensure the regular action of the bowels.

Remarks.—This case is full of interest. It shows the fact that large collections of matter may take place in the neighbourhood of the rectum, without being preceded by the usual inflammatory symptoms, or, indeed, by any that are distinctly diagnostic; and no less clearly does it prove the great importance of freely opening abscesses in that situation at an early period. To the refusal of my patient to submit to this practice, all the subsequent mischief was to be attributed. Inflammation, once set up in a tissue possessing such feeble vitality as the adipose (especially in individuals of an unhealthy habit), is very little under the control of antiphlogistic treatment. Leeches, which, undoubtedly, should be applied in large numbers, followed by poultices, relieve the pain, but do not materially retard the sloughing process when it has once commenced. Indeed, we can do little more, when the case has so far advanced, than support the patient as much as possible, and aid the escape of the sloughs as soon as they are loose; for these, lying in contact with the living structure, cannot fail to prove a source of irritation.

Most abscesses, near the rectum, forming, as in the above instance, in a passive manner, are perhaps connected with some cause of obstruction to the return of blood through the hemorrhoidal veins, and hence frequently coexist with piles. In our present case, the secretions of the rectum probably found their way through the hemorrhoid, and in fact, what is called "a fistula" into the surround-
ing tissue, and induced an irritation of the abscess; and, in a varicose state of the adipose tissue of

the perineum, with the consequent imperfect circulation in the capillaries, is quite sufficient to explain the occurrence of sup-
puration.

CHARGES PREFERRED BY THE LATE SURGEONS OF THE PRESTON DISPENSARY

AGAINST THE PHYSICIANS OF THAT IN-
STITUTION.

To the Editor of THE LANCET.

SIR,—As you have always evinced a desire to rectify abuses in the medical profession, and to expose the misconduct of public officers to that obloquy which it merits, we trust you will permit us to lay before the medical public, through the pages of your journal, an instance of intrigue and faithlessness, that is, perhaps, unique in the annals of our medical institutions.

The principal medical institution in Preston is a dispensary, which was established in 1809. At first it was managed by two or three physicians, and a house-surgeon. In 1830, three surgeons were appointed to assist in the labours of the establishment. The two senior physicians then consigned over to their surgical colleagues, such operations as they had previously performed; but the junior physician, Dr. Moore, tenaciously clung to his share of the surgical cases, and continued to act as a general practitioner, at the same time that he laid claim to the honours and the fees of a physician in private practice.

Thus the business of the dispensary continued to be managed, until the senior physicians withdrew, and junior physicians were appointed. These gentlemen, imitating it is supposed their senior, took their station as general practitioners also. There was no division into medical and surgical practice, but each honorary officer took all cases indiscriminately that were presented on his day for the reception of patients. There were, ostensibly, three honorary physicians and three honorary surgeons attached to the institution; and so the rules enjoined and the reports continually declared; but in reality, there were six general practitioners. Notwithstanding this anomalous state of things, the greatest harmony seemed to prevail among the honorary officers up to December last. Then an alleged irregular attendance of some of the medical officer induced the sub-committee (whose duty it was to see that the affairs of the institution were regularly conducted) to inquire into the cause of the neglect, and where th

office rested. Dr. Moore (whether to screen himself from censure, or not, he best knows) went to the sub-committee clandestinely, and told them, that they must "look to the doctors," and they need not fear if some of the medical officers were to resign, as their places could readily be supplied. The truth of this statement Dr. Moore afterwards chose to deny, notwithstanding the united testimony of several of the members of the sub-committee, alleging that he had merely directed the sub-committee to "look after the shop," meaning the dispensing of the medicine (the Doctor's phraseology frequently needs interpretation); but, unfortunately for himself, he had declared to a medical friend shortly after meeting the sub-committee, that he had been telling them "to look after the doctors." After hearing the testimony of that friend, he reluctantly admitted that he had made use of such an expression, but said that it was merely used "by way of a joke." Some people, however, have such an odd way of joking, that no persons but themselves can conceive how their expressions can possibly be construed into a jest. The gentlemen of the sub-committee thought that the Doctor was in earnest, and as they had not the candour or honesty to bring a charge against the offenders (and they well know who they were), they hit upon the expedient of procuring a book, in which they resolved that the medical men should enter their names, and the time of their attendance, whenever they came to the Institution. In this they exceeded their powers, for their duties were defined to be simply to observe and report to the general committee.

The book was first presented to the surgeons, who, not aware of any neglect on their part, and knowing that the sub-committee had no authority to enact any regulation for their guidance, naturally felt indignant at what they regarded as an insult; and immediately entered a protest in the book against the measure. This protest the physicians, and Dr. Moore with the others, afterwards signed. The sub-committee were greatly displeased at this resistance to their assumed authority, and not a little surprised to find that the instigator of the whole affair was arrayed against them. The general committee was called together, and the medical officers, as part of the committee, attended the meeting. An attempt was there made to force the obnoxious regulation, but meeting with more resistance than they seemed to anticipate, the authors of the measure, with a very bad grace, consented to modify it, obliging the house-surgeon to be the inspector, instead of attempting to compel the honorary officers to be self-inspectors.

The treatment which the medical officers met with at that meeting, was such that they thought they could no longer continue

to serve the Institution, and shortly afterwards, they all sent their resignations to the secretary, offering, however, to fulfil the professional duties until successors were appointed. The committee accepted the resignations, but took no steps to fill up the vacancies. Repeated meetings of the medical officers took place, at the suggestion of Dr. Moore, and at his house. He several times expressed great pleasure at seeing the unanimity that pervaded the meetings, and frequently reminded his colleagues, in his peculiarly elegant language, that "there must be no splitting," but "all must pull together." He required a pledge from his colleagues "that no opinion should be given to the committee, or to the subscribers without a general consultation, and that all must go out or remain in together; adding "If any question be put to me, I shall say, 'I can make no reply till I have first consulted my colleagues.'"

In May a meeting of the subscribers to the Dispensary was called to consider the resignation of the medical officers, and make some "verbal alterations" in the rules of the Institution. Dr. Moore drew up a memorial to be presented to the meeting, in which he gave a partial statement of the causes which had led the medical officers to resign their appointments, and in which he declared the differences between them and the committee to be "irreconcilable." In deference to his opinion, four of his colleagues signed this address, and were thus prevented from being personally present at the meeting. When the subscribers met they expressed no opinion of the cause of the resignation, but they confirmed all that the committee had done, and passed a resolution to exclude four of the honorary medical officers from the committee, thus actually attempting to punish them for having resisted a most arbitrary and uncalled-for measure. The appointment of successor was still not made. When two of the surgeons became acquainted with the result of the proceedings of the subscribers, they were disposed immediately to withdraw their services; but as it had been previously agreed to act in concert, they were desirous of first ascertaining the feelings and intentions of their supposed friends, before they took any final step. Accordingly they called upon Dr. Moore, who met them with a smile, and the salutation of "Well, gentlemen, I know what you have come about, but I have made up my mind to stay, who ever goes out, and I have told one of the subscribers so." When charged with violating his pledge, he replied, "Well, perhaps I have accomplished it, but so I have done." He then threw upon the table some observation which changed the subject, and had suddenly discovered that "it would not do to quarrel."

body of subscribers," that "the poor should not be made to suffer for the faults of the committee;" and made use of a variety of other sentimental expressions of "humanity," which he had entirely forgotten or had wholly overlooked, for five months, during which the affair had been pending.

The surgeons afterwards found to their surprise that the other two physicians of the charity, Drs. Alexander and Norris, influenced by Dr. Moore's representations, had also come to the determination to sacrifice their word and consistency, to what they conceived to be their interest. Thus was explained a previous declaration of Dr. Moore, that he knew that there were medical men who would serve the charity if the number of its officers was reduced.

After such an instance of duplicity and deception, the surgeons considered themselves bound, for the honour of the profession, to separate themselves entirely from the physicians, and to act independently of them. They accordingly withdrew from the Institution, and left the physicians in peaceful possession, apparently to their great satisfaction. Although they had received official intimation that the committee had accepted their resignations, they knew that no apology would be offered for the insults which had been given them, and that they would labour under the disgrace of having one of their number excluded from the committee and have an inspectorship appointed over them.

We regret, Sir, the necessity of this exposure, and disclaim all feelings of personal animosity; but we conceive that it is our duty to expose conduct so unprofessional, and so inexplicably mean as that which we have brought to light. We offer no comments upon the previous statements, nor attempt to ascribe motives to individuals, but rest satisfied with a simple declaration of the truth, assured that we shall have the sanction of every honourable man to the course which we have pursued, and that reprehension will be bestowed where it is due.

We have the honour to be, Sir,

Your obedient servants,

ROBERT BROWN, } Late Hon. Surgeon,
RICHARD INMAN, } of the Preston Dispensary.
JAMES HARRISON, }

Preston, Lancashire, Nov. 12, 1835.

THE MEDICAL CONTRACT FOR THE

NORTH AYLESFORD UNION.

OF THE LANCET.

A journal eminently devoted to the rights of the poor, and as a Member of the Committee, to point out to you the

present character of the medical aid furnished to the sick poor of the several parishes forming a Union in Kent, and called "The North Aylesford Union."

The Union comprises fifteen parishes, which I shall arrange alphabetically, and place the number of miles that they are distant from the residence of the medical officer (who does not even live in the Union), in the case of each parish:—

	Miles.		Miles.
Cliffe	5	Hilling	5
Chalk	6	Huddesdown ..	7
Cuxton	4	Moepham	9
Cobham	4	Northfleet	10
Denton	7	Nursted	8
Frinsbury	2	Shorn	5
Halling	5	Strood	1
Higham	4		

All taken from the nearest point. I am sorry that I cannot at present add the population of each, but some, as those of Strood, Frinsbury, and Northfleet, are considerable. On the forming of this Union it was at first intended to make two divisions of it, and a notice from the guardians, signed by their clerk, was published, stating that a medical officer was wanting for each division, at salaries of £90 per annum each; for which sum each in his district was to furnish aid and medicines, in all cases, under the direction of the guardian, or the relieving officer, 10s. in addition being allowed for each case of midwifery. For the division including Chalk, Denton, Hfield, Huddesdown, Moepham, Northfleet, and Nursted (although Gravesend, a large and populous town, and duly supplied with medical men, is within 5 or 6 miles of the most distant of these parishes, not one medical man was found who would pretend to perform so arduous a duty for so inadequate, and, as regards proper and efficient assistance and a due supply of remedies, so contemptible and disgraceful a sum; and, for the other division, including Cliffe, Cobham, Cuxton, Halling, Higham, Frinsbury, Shorn, and Strood, one only offered from among about twenty in Rochester (where the one resides) and its neighbourhood; and whether from necessity or otherwise, the guardians actually appointed this one for the whole Union, with the united salaries.

Now, Sir, passing by any observation on this sacrifice of professional respectability, this contemptible value for medical services, offered and accepted, I would ask what opinion must a humane mind form of the views and intentions of these "guardians," so called, of the poor, towards sick paupers? What must be the opinion of the poor themselves? It appears to me that had the "guardians" boldly advanced a resolution that medical aid to the sick poor should be difficult to obtain, they could not have hit on a more effectual plan. In cases of fracture or other accidents, hemorrhage or in-

inflammation of the lungs, life may be lost by the very delay caused by having many miles to send; but even in ordinary cases of illness, that the poor creatures should have to send or attend personally at so great a distance, seems a monstrous cruelty. I am told that the guardians think it best to have but one responsible medical officer, whom they require to be a legally-qualified practitioner, leaving to him the supply of necessary aid. But do they require also, and see, that the aid so furnished, is that of "qualified" persons? Can they expect the medical officer to expend so much of his paltry salary as a qualified person would have a right to expect? I think, Sir, that these are matters for the serious consideration of the "guardians," ere a coroner's jury remind them of their duty.

In the furnishing of medical aid to the Unions in general, and to this Union in particular, one would almost be led to consider that the very lives of paupers were put in competition with a few paltry pounds sterling. Many other observations suggest themselves to me on this occasion, but the communication of Mr. Rumsey coming before me, and having reason to expect that his questions will be generally considered and replied to by the medical men in this neighbourhood, I shall for the present suppress further remarks on the matter, and am, Sir (authenticating my communication in a private note), yours truly

HUMANITAS.

Rochester, Nov. 9th, 1835.

GERMAN JOURNALS.

Hufeland and Oken's Journal. — June and July, 1835.

The two last Numbers of the above journal, which we have received, contain:—

1. Practical Observations, by Professor FLEISCHMANN, of Erlangen. 2. On an Epidemic of Angina Parvula, at Oldruff, in 1830, by Dr. KREGELEIN. 3. A Few Remarks on the Diagnosis of Intestinal Catarrhes, by Dr. ALBERS, of Bonn. 4. Practical Remarks by Dr. LOWENHARD. 5. On Thymic Asthma, by Dr. HIRSCH, of Königsberg. 6. Two cases of Religious Madness, with remarks, by Dr. WEGEL. 7. On the efficacy of "Argilla depurata" in the Diarrhoea of Children, accompanied with vomiting, by Dr. G. E. DERN.

We shall notice only the most remarkable of the above communications. The first is contained in the "practical observations" of Dr. FLEISCHMANN.

PRESERVATIVE EFFECT OF BELLADONNA AGAINST SCARLATINA.

Some experiments with this medicine were made on fifty-two children during an epidemic of scarlatina, and though not on a sufficiently extensive scale to have much weight, deserve to be added to the number of those instituted for a similar purpose.

The extract of belladonna (2 grs. to an ounce of distilled water) was administered to fifty-two children, of from six months to fourteen years of age. Each patient took, morning and evening, as many drops of the solution as he counted years, and this dose was in some instances increased. The remedy was thus administered for the most part during five weeks,—the duration of the epidemic.

Of the fifty-two individuals forty-eight remained free from any attack, and four were affected with the disease. In two families, where the children commenced taking the remedy immediately on the disease attacking one of the family, all the children remained free from contagion, although they were in constant communication with the affected individual during the whole course of the disease.

In several cases the author remarked symptoms of the action of the belladonna a few days after its use; such as disturbed nights, slight inflammation about the throat, salivation, thirst, torpor, dilated pupil, pain in the head, vomiting; and one girl, six years of age, was seized, on the 10th day after the first dose, with fever, pain in the throat, restlessness, and delirium. On the following day the whole of the body, except the face, became red, and was covered with miliarial vesicles: this continued a couple of days, and then disappeared.

A boy, four years of age, who had taken the belladonna for three weeks, became very uneasy and disturbed on the 5th of March; on the 6th this had passed off. On the 9th, the child, enjoying perfect health, was covered in all parts of the body, except the face, with a red eruption, which remained till the 11th. On the 12th it diminished, and had completely disappeared on the 13th.

A child, eighteen months of age, who had taken the belladonna six days, was seized with difficult deglutition, inflammation of the cervical glands, excessive thirst, and general redness of skin. The eruption was much increased

on the second day, and the child was well on the fifth.

From the above-mentioned experiments the author concludes:—

1. That the belladonna seems to have an influence in counteracting the contagiousness of scarlatina.

2. That in some cases it diminishes the susceptibility for the contraction of the disease, though it does not altogether remove it.

3. That when the disease does occur during the use of belladonna, its character is much more mild than in ordinary cases.

4. SCIATICA CURED BY OPENING THE SCIATIC NERVE.

In many cases (says Dr. LOWENHARD, the author) of obstinate sciatica, the cause of the disease is unknown, and all the remedies which are applied fail to relieve the patient from the dreadful and constant suffering to which he is exposed. The effect of division of the branches of the third pair of nerves, has induced some surgeons to recommend a somewhat similar operation for those of the extremities; and M. Jobert a few years ago divided and removed a portion of the sciatic nerve for obstinate sciatica, but we do not at this moment remember what the result of that bold operation was. The following case, though not exactly of the same nature, deserves to be recorded.

Case.—Mr. B., 38 years of age, of good constitution and sanguineous temperament, was seized with pain in the region of the left hip-joint, in consequence of some violent exertion. The pain continued fixed for about two months, and then extended downwards in the direction of the sciatic nerve. After the expiration of six months, the pain became so severe that the patient was unable to place his foot on the ground. He now demanded medical aid for the first time; various remedies were tried in vain, and he came under the author's care in six months afterwards. The patient was now much emaciated; the injured limb particularly reduced in size, and the heel so painful that the patient could not stretch out his foot without aid, and had the most acute

A cord about the thickness of a finger was felt under the skin, in the direction of the nerve, which was very tender to the touch; the urine deep red,

and throwing down a dirty sediment. After some reflection the author conceived that perhaps the swollen nerve contained a watery fluid, as in the case mentioned by Richter (*Speciel. Thera.* part 2, p. 79), but how to give issue to this fluid was the question of most importance. A simple incision would easily have produced the desired effect, but it was necessary at the same time to impress a stimulus on the muscular system; the author therefore determined on employing the actual cautery, which was applied immediately to the nerve, where it passes between the trochanter major and the tuberosity of the ischium: on the iron being pressed with some force into the bottom of the wound, two to three ounces of a yellowish-gray fluid came away. The wound was then dressed with some mild salve, and as the patient was nearly in a fainting condition, he took a restorative.

The day after the operation, the patient was more oppressed and weak, uneasy, and with a very small pulse. Some stimulants and cordials were given. On the 21st same state; the wound still discharges a little fluid, and was dressed with ung. canthar. The pain of the foot has now changed into a dull sensation, the patient slept a little this night for the first time since many months.

22. Passed a good night; he can now stretch out his foot without aid; the wound suppurates abundantly. In the course of eight days the patient recovered a good deal of strength; a considerable quantity of a grayish fluid, different from pus, was discharged from the wound. The injured limb increased rapidly in size, and after a lapse of some months, during a part of which the same discharge continued, the patient was perfectly cured.

There can be no doubt, from several cases which have been published, that water may accumulate in the tissue uniting the medullary filaments which compose a nerve, nearly in the same way as in hydrocephalus. The author is inclined to attribute both phenomena to a similar cause, namely, chronic inflammation. In the present instance it seems probable that the capsular ligament of the hip-joint was also involved in the disease, and that the quantity of fluid subsequently discharged was in part furnished from the joint itself.

5. THYMIC ASTHMA.

The attention of the profession, says Dr. Hirsch, of Königsberg, was first drawn to this peculiar affection of children, in the year 1830, by Dr. Kopp, who gave it the name of "Asthma Thymicum;" since then several interesting observations have been

made by the German physicians, of which the author of the memoir now before us gives an ample *renuim*.

Asthma Thymicum, or, as it is more generally called in Germany, "Kopp's asthma," attacks children between three weeks and eighteen months, but prevails most between the fourth and tenth month. It is characterized by accessions of spasm in the air-passages, and general irritation; the respiration becomes suddenly suspended, and we observe only a whizzing, very fine, small, and imperfect inspiration, an embarrassed passage of the air through the rima glottidis, which is spasmodically contracted in the highest degree. The tone has a certain analogy with the crowing inspiration of whooping-cough, but it is much finer, higher, and less deep; the closest analogy we can find for it, is in the spasm which frequently attacks certain hysterical women. In certain cases we remark from five to six whistling, deep, and difficult inspirations, alternating with scarcely observable expirations, and which resemble the tone in a very severe degree of croup: in the most dangerous cases the breathing is *completely* suspended; the fine inspiratory scream is then perceived only at the commencement of the paroxysm, being immediately suspended, together with the breathing; or on the cessation of the attack it gives the first indication of returning life; it is quite characteristic of the disease, and pathognomonic. The remaining symptoms of the paroxysms are the natural result of the spasm of the respiratory organs; the child is violently contorted in the bed, or under a more severe attack seems quite overwhelmed; the face is distorted by the expression of painful anxiety, is of a blue-red, or pale colour; the nostrils are expanded, the eyes fixed, the hands cold, the thumbs contracted; the excretions pass involuntarily. Within a half, or one, two, or three minutes, the paroxysm goes off: the child utters a painful and uneasy cry, and soon becomes gay and playful. It is only when the constitution is weak, or when the attack has been very violent, that the child remains for some time pale, flaccid, and with a tendency to sleep. In the intervals of the paroxysms the child is gay, the respiration quite unembarrassed, and the patient seems to enjoy perfect health. Kopp gives as peculiar symptoms the two following, viz., the tongue during the inter-

mission remains projected a little beyond the teeth, and the pulsation of the heart can scarcely be felt; but in several genuine cases of this disease the first symptom has not been observed, and even in healthy children the pulsation of the heart is not readily felt. The paroxysms are generally single, with an interval of eight or more days, but by degrees they occur more frequently, and even reach ten to twenty in one day; in this period the child frequently goes off suddenly; however, in several other cases a second period sets in, which is characterized by general convulsions of an epileptic nature. The cerebral and respiratory paroxysms never occur together, but alternate; and now, even when the child is free from the attack, the lumbricales and the adductors of the thumbs become spasmodically contracted, and give the hand an appearance of deformity. The child now commonly dies in a paroxysm between suffocation and apoplexy; or, in many cases, when the accessions have been severe from the outset, he is carried off suddenly, as if by nervous apoplexy, without asthma, rale, or any agony; in this way the child of Professor Eck died, *Rust's Magazine*, xx. and several other children.

On examination of the body after death, we find a blue colour of the skin; congestion of the brain and lungs; softness of the right ventricle; the foramen ovale sometimes open, and in all cases the thymus gland is remarkably enlarged. The long and broad diameters of the gland are remarkably enlarged, but chiefly its thickness; in the latter case the lungs were frequently pushed down by it into the lower part of the cavity of the thorax; in other cases the thymus was found closely connected with the great arterial and venous trunk of the chest or neck. The tissue of the gland appeared normal, or (what was more common) was more fleshy, red, and dense than natural, but never showed any trace of hardening, suppuration, tubercles, &c. When divided, it frequently gave out a peculiar "chinous-looking" fluid. In the cases where the gland was weighed, a good deal of difference was observed. Kornmann found the largest to weigh 14 drachms; Pater, 1½ oz.; the author of 9½ drachms; Kopp varied between six and

very various; the quicker and more severe the paroxysm, the shorter, of course, is the disease. It commonly lasts several months. Dr. Eck's child died on the third week; Rullman's (*Kopp*, p. 64), after a suffering of twenty months. When a cure takes place, the symptoms gradually decline, and the disease goes off in one to three weeks; but in other cases the spasms are not completely removed before one or two years.

Children of a scrofulous habit are particularly exposed to this disease; in many cases the mothers were of a weakly phthisical constitution, and several writers have remarked a family predisposition. Boys are more frequently attacked than girls. It holds good also with respect to adults, for from Frank's observations (*Prac. Med. Princpt.* II, p. 760), men are more exposed to asthmatic affections than women, in the proportion of six to one.

The diagnosis of this disease is not very difficult, and it bears but a slight analogy to a few of those mentioned by authors. Millar's Asthma is a disease so loosely described by English writers, who have confounded various and different affections under the same name, that it is difficult to say what particular malady is meant; however, it evidently differs from the disease which now occupies our attention, by the nature and length of the paroxysms, and by the acute march of the disease.

Gillis has described, as a symptom of chronic hydrocephalus, a peculiar cough, which afflicts the child when awakened from sleep; the infant becomes stiff, the whole body blue, and he remains for a minute without breathing, until the respiration recommences with a loud cry. This symptom is constant in the latter period, and thought bears much resemblance to "Kopp's asthma," may be distinguished from it by the other symptoms of hydrocephalus.

From an examination of the symptoms and morbid anatomy of this disease, the author concludes that it consists, —

1st. In a periodic tonic spasm of the respiratory organs, and perhaps the heart, which, as the disease advances, extends to the brain and spinal marrow, giving rise to epileptic convulsions and death. 2nd. In an enlargement of the thymus gland, which, by its pressure on the lungs, heart, and other organs, more or less disturbs

varies very considerably in size and weight; in small feeble children it weighs (according to Haugsted's experiments) scarcely a drachm; the average weight may be estimated at from two to three drachms; it increases up to the second year after birth; remains stationary to the eighth or tenth year, and then gradually becomes absorbed to the sixteenth or seventeenth, when nothing but a rudiment remains. Its specific gravity also varies; in the fœtus of eight months it is 1.099; in new-born children 1.071; in a child fourteen years of age 1.020, and at a later period is lighter than water. In the asthma thymicum, however, the weight of the gland is very considerably increased, and varies from six to fourteen drachms, while its thick fleshy structure contrasts strongly with the soft spongy appearance of the normal gland.

Having established the coincidence of enlarged thymus gland with the disease in question, the author proceeds to answer several objections which may be opposed to the idea of the asthmatic symptoms being really dependent on the abnormal state of the thymus. Our limits will not permit us to follow him through these; we shall therefore pass at once to the treatment.

The prognosis of the disease, though a very dangerous one, is not hopeless, especially when the child is strong, and not subject to catarrhal affections, when the case has been seen early, the paroxysms are not very frequent, and before the appearance of general convulsions.

In the treatment, we must not lose time by the employment of any temperizing remedies. The first and most pressing indication is evidently to moderate the spasmodic attack; this is best done by the administration of small doses of the "aqua laurocerasi," which are to be gradually increased. When given with precaution, the remedy is not dangerous, and has the most beneficial effects. When the spasms are very violent, a small dose of musk may be added; in addition to these, asafoetida, zinc, and particularly the sulphate of zinc, have been given with very great benefit. The second object we have in view is to diminish the state of congestion towards the heart and lungs, by proper diet, by frequently-repeated (every four to eight days) local bleedings, blisters on the chest, and other similar

of a new-born child

means, regulated of course by the strength and constitution of the child.

Several physicians have endeavoured to act immediately on the enlarged gland, by the administration of anti-scorfulous resolvent medicines (and apparently with much success), as mercury, digitalis, iodine, &c. Twenty years ago, A. Burns proposed to extirpate the gland by making an incision in the anterior part of the neck, between the sterno-hyoid muscles; the finger was then to be worked down into the chest, between the sternum and gland, and the latter removed with the aid of a polypus hook; but this operation has never, as one may well conceive, been attempted on the living body. The following case, selected from amongst those published at the end of the memoir, will serve to give an idea of the progress of the disease.

CASE.—Victor V. M., twelve months old, suffered at an early period of birth from diarrhœa; this however soon ceased, and the child became healthy; when, at the age of five months, he was seized with chronic bronchitis; from this time the mother remarked a symptom which she had not previously noticed, viz., that the infant on awaking from sleep, or immediately after, had the respiration suddenly suspended; the attack however soon went off, and was generally mild in the commencement, but after the lapse of some time the paroxysms became more severe. The breathing was now completely suspended, the face expressive of great anxiety, pale, or at times purplish, and the body convulsively bent backwards. After one or two minutes the child recovered from the attack, drew a few fine-deep inspirations, and then uttered some sharp cries, after which he became gay and apparently well. The nature of the disease was evident; leeches were applied to the breast, followed by a blister, and small doses of calomel with rhubarb were administered.

This treatment at first seemed to be attended with benefit; the paroxysms were suspended for a week, but soon returned with increased violence, even every one or two hours; muck was now given without any amelioration, and after a lapse of eight days the child was carried off in a fit of suffocation, without any general convulsion.

The body was examined thirty hours after death.—The thymus gland was remarkably enlarged, and filled the whole of the anterior mediastinum; from the middle of the gland a process was sent off, which closely embraced the common jugular vein; the substance was very dense, and it weighed 94 drachms, or 570 grains. The right lung was remarkably compressed, but sound in struc-

ture. The appearance of the heart was normal; the right ventricle was very soft, the left was firm; the foramen ovale was closed. The head was not examined.

On Dropsies, connected with Suppression of Respiration and Congestible Urine. By J. OSBORN, M.D. Lond. &c. Sherwood, 1835, pp. 64.

THE condition of the urine has received less attention from the Scotch school of medical writers, and from all the theoretical schools of the continent, since the time of Hoffman, than its importance in pathology and in practice would warrant; partly owing to the horror of *humoralism* prevailing, and partly in consequence of the want of good chemical tests of its constituents, or to the exaggerated views with which certain ignorant empirics and mountebanks choose to mislead the community. The orthodox practitioner could not but treat the glass with disdain in which the quack had pretended to see the disease; and, "to cast" the fortune of his patient; and to avoid giving occasion to odious comparisons, he could uncharitably abandon signs which he knew so rarely how to recognise, much less to interpret; overlooking those very critical points on which Hippocrates, Galen, and the ancients, made the whole course of disease to hinge, but, unfortunately, the authority of the ancient Greeks, and the light of their genius, were hidden from the community amongst us, by their works not being translated, as was the Bible, into English. Galenists, Brownists, and theorists of every class, found it easy, in the last century, to divert the profession for a time from those extensive and easily-discerned changes in the secretions which the ancients had signalized, and to direct their attention only to the beatings of the pulse, to the tongue, and to the extreme vessels.

The investigations of chemistry, applied to the urine by Berzelius, Prout, Marcei, and others, have already become of practical importance; the presence and the proportion of urea, the phosphates, bile, and sugar, deserve in many cases more attention than any other symptoms. In pathology is more strictly confined, probably be found always in connection.

Albumen, so constantly occurring in

dropsy, and coagulating in the urine when exposed to heat, was first detected by Dr. Wells. Dr. Black hall made further observations, and confirmed the announcement of Wells, that in a great number of dropsies, in which the urine coagulated by heat, there was evidence of inflammatory action, and that in such cases, bleeding was productive of very marked benefit. Dr. Crompton recorded some cases in the "Memoirs of the Dublin Medical Association," to confirm the evidence in favour of bleeding. The inquiry rested at this point until Dr. Bright made the striking observation, that coagulable urine was connected with a diseased state of the kidneys. Drs. Christison and Gregory shortly afterwards published eighty-seven cases, and amongst those, the granular deposit in the kidneys was always detected when examination after death took place. Dr. Osborne has, in the volume before us, presented the results deducible from thirty-six observations, so that the evidence relative to this disease seems now sufficiently extensive to positively determine its nature. Still, so difficult is "judgment" in pathology, that the relation of dropsy to the granular condition of the kidneys is by no means yet established. Dr. Osborne was prejudiced against the opinion of Dr. Bright, in connecting coagulable urine with diseased kidney, and professes only to have been converted by the force of facts, some of which, with the modification in the treatment advocated by him, we proceed to notice.

Dr. Osborne has described the appearance of the kidneys very succinctly and clearly.

"When an injection is thrown into the artery, even in the most successful manner, it will not penetrate into the grayish deposit. The cortical portion of the kidney is the chief seat of the deposition; yet we sometimes find it filling up, and encroaching so much on the other part, that the tabular portion is limited to small, insulated portions; and in these cases the tubuli increase in density, and become more confused together, the nearer they approach their termination in the mammillated processes. In some of the most acute cases I found the lining membrane of the pelvis and upper portions of the uterus in a state of the highest vascularity, resembling crimson velvet. The changes produced on the size of the vessels are remarkable, and in my opinion, to follow this rule,—in some cases, the kidneys are smaller than the natural standard; in some cases they are re-

duced in size, and become hard in proportion; the cortical structure appearing to be removed, and replaced by the gray deposit."

The smallest quantity of albumen is detected by the bi-chloride of mercury; but when this is used the urine should be acid, or many of its neutral salts will be precipitated. From frequent observation, we can declare that the acid urine of healthy persons, particularly when they have been taking severe exercise, yields a precipitate with this delicate test; and when influenza was last prevailing in London this precipitate was unusually abundant. Nitric acid, when there is more albumen, is a good test. Heat coagulates the albumen only when it exists in considerable quantity: when, therefore, the urine is said to be albuminous, it is quite necessary to state what tests have been employed. Dr. Osborne remarks, that,—

"The examination of the urine in this disease must be conducted according to one fixed rule, otherwise we shall constantly meet with apparent contradictions. The urine should be that which is passed in the morning before breakfast. It should not be examined till it has cooled. It then is usually of a pale citrine colour, semi-transparent or translucent, but not transparent like healthy urine; and at the bottom of the vessel there is an opaque, whitish cloud, consisting of the mucus of the urinary passages, and differing from healthy mucus by its greater density and opacity; while in other cases it differs from the healthy state by containing no mucous cloud. On heating this urine, in a spoon, over the flame of a candle, white coagula are formed in those portions of the fluid next the metal, long before the heat has advanced to the boiling point, and when the heat is continued afterwards, the coagula become more firm and distinct. The lesser degrees of coagulability are signified by its not taking place till the fluid has boiled, or till some of it has been evaporated; by no coagula forming, and the fluid being rendered merely turbid; and, lastly, by throwing up a froth when boiled, which appears to be produced by the smallest quantity of albumen that can satisfactorily be tested by heat. I may here mention, incidentally, that I use this mode of examining urine in other diseases beside dropsy, and without any expectation of meeting albumen."

The proportion of urea, and the specific gravity of the urine, are diminished in this disease. The quantity of urine is not much altered.

Is coagulable urine invariably the result

and sign of a granular, morbid condition of the kidney? Dr. Osborne answers this question in the affirmative, and animadvert with some severity on those who think *further observations are required*. He states that out of thirty-six cases, nine autopsies evinced the disease of the kidneys in every instance; while the symptoms, causes, and collateral circumstances of all the other cases, led to the same conclusion:—

“The negative evidence in my possession is too copious to be detailed. It is, however, decisive as to the question at issue. It consists of numerous cases of dropsies, connected with diseased liver, impediments of circulation, or respiration, or general debility, which terminated fatally, in which the urine was examined before death, and found not to coagulate, and the kidneys were found to be free from disease; also cases ending fatally, but unconnected with dropsy, in which the kidneys were healthy, and the urine did not coagulate. This evidence appears to me peculiarly valuable, inasmuch as during the last three years I have anxiously sought for every opportunity of examining the kidneys of every individual in whom the urine had been examined during life; and in no one instance have I met with coagulable urine without diseased kidneys, or healthy kidneys with coagulable urine.”

Dr. Osborne has laid down two propositions, between which there seems to us to be some discrepancy. He puts this disease renal dropsy, and thereby seems to assert that the disorganization of the kidney—the secreting gland—is the cause, the source of dropsy,—accompanied by coagulable urine. An alteration in the secreting gland will doubtless account for an alteration in the properties of the secretion; but an alteration in the fluid from which the secretion is eliminated *may also account for* an alteration of the secreted product, and effect the precise change in the kidney described by Dr. Bright. If, as Dr. Osborne contends, dropsy with coagulable urine is attributable to *suppressed perspiration*, it inevitably follows that a change in the proportions or nature of the constituents of the blood precedes the disease of the kidneys, and that this alteration of the kidneys is an effect of the modified fluid which those organs secrete.

Dr. Osborne's system of treatment is founded on the assumption that the “continuous suppressed perspiration,” which he proposes to denominate “Anidrosis,”—is

the most general cause of the disease. Suppressed perspiration, we may remark, is a very fallacious term, and may indicate two entirely different states of the cutaneous surface; for in popular language it merely denotes dryness of the skin; and this state of the skin may arise from its temperature being a few degrees higher than usual, or from the fluids with which it is saturated having less elastic force. But the practice of Dr. Osborne appears to have been remarkably successful, and the results alone—*independently of any theoretical consideration whatever*—decide on the merits of a therapeutic system. Of the 80 cases treated by Dr. Gregory with diuretics &c., 45 died; of 36 cases treated by Dr. Osborne, only nine terminated fatally; in the one series 56, in the other 25 per cent. perished: a proportion very favourable to the latter treatment. The numbers are not sufficiently numerous to furnish exact data of the absolute mortality of this disease when under medical care; but 24 deaths in 116 cases,—16.6 per cent.—is a high mortality, which would place the dropsy nearer to diabetes and phthisis, than to fever or inflammation. Bleeding, purgatives, and other remedies, were employed in complicated or obstinate cases; but Dr. Osborne thus describes the most essential parts of his treatment:—

“When a patient was placed under my care, with general oedema, coagulable urine, and dry skin, I directed him to be kept in bed, in order to diminish the area of the surface, which is usually disposed to be cold. It had happened frequently that, by external heat alone, an improvement both in the quantity and quality of the urine, and a material subsidence of the oedema, have taken place. The first medicine ordered was usually a purgative; and in the choice of this, in order to avoid ambiguity as to its mode of action, I abstained from the use of all those articles which are reputed diuretic, such as compound of jalap, or superacetate of potash; and I generally employed the scenna mixture. I then commenced a diaphoretic course, by administering foot-baths, hip-baths, or general bathing the feet with a mixture of water or of vapour, according as they appeared to agree best with the individual case, at night at the hour of going to bed. The patient also took at night eight grains

“I have seen that some employment of warm-baths early in the less liability to coagulate to perspire in every individual sleep, under the hour expedient.”

of *Pulv. Jacob.* var. 4., of *Pulv. Ipecac. c.*
Opio, and 10 grains of *Confect. Aromat.*"

We have read Dr. Osborne's elegantly-written book with much pleasure, and do not doubt, from the new and interesting facts which it embodies, as well as from the instructive manner in which the subject of the disease is treated, that it will shortly be in the hands of all who take an interest in medical discovery. On this account we have freely stated whatever objections we consider to lie against Dr. Osborne's theoretical views; while we have detailed the result of his observations and experiments in the pathology and therapeutics of those dropsies which are accompanied by coagulable urine, and connected with disorganized kidneys.

THE LANCET.

London, Saturday, November 21, 1835.

JUDGING by appearance, the question of Medical Reform made some progress—we are at least assured that it made much noise—in the Irish capital during the week preceeding the last. On former occasions this subject has always been touched by the Professors of Dublin with a degree of delicacy and reluctance which attend the handling of a dangerous topic. The speakers seemed to feel as if some fatal catastrophe was necessarily involved in its discussion. On the present occasion, however, the fearful question—from the contemplation of which the most courageous at one time used to shrink—was fairly brought before the public; and examined with a degree of freedom and familiarity that would indicate the total loss of its pristine terrors. To Mr. ELLIS, one of the lecturers in the *Peter-street Medical School*, the merit of being the first to approach this hazardous subject appears to be due. In a discourse recently delivered in the *Medical Establishment* to which he belonged, he not only discussed the leading question, but had, as his contemporaries

might think, the temerity to announce his intention by public advertisement. No serious consequences, however, of which we have heard, have as yet followed the rash undertaking. He not only survived the exposition of a multitude of medical abuses in the medical institutions of these countries, and of absurd enactments in the statute-book of medical law, but, strange to say, he was cheered throughout his statement of the case of reform by a numerous assembly of students and practitioners. It is surely a step gained, in *Ireland*, in the progress of the question, to convince, by actual experiments, the hypochondriacal advocates of improvement in Dublin, that there is, after all, nothing dangerous in the entertainment of a topic in which mere reason and evidence are combined. To Mr. ELLIS are the profession in that quarter indebted for the discovery.

So far, therefore, as the act of divesting the theme of its imaginary horrors, and of calling general attention, by personal appeal, to its examination, is a meritorious one, we cordially concur in the favourable estimate which we hear was formed by his auditors of the manner in which Mr. ELLIS discharged the duty he had undertaken. But if our report of the lecture be correct, we cannot state that we think his enumeration of medical abuses was so comprehensive as it should have been in a discourse professedly devoted to their discussion. Some of these omissions are indeed so remarkable, that we mean to notice them. In our experience, every sound reformer has always looked upon the system of *compulsory* apprenticeships as one of the most baneful usages of the surgical profession in *Ireland*. They have also ever thought the scale of fees to witness hospital practice most oppressively and iniquitously unjust. Yet upon these two important items in the catalogue of medical abuse, no opinion was given in the oration of Mr. ELLIS. In these omissions, which we presume were accidental, he was neither just to himself nor to the question which he designed to

advocate, and he ought to have foreseen that the absence of condemnation of such glaring and notorious features in the picture of medical economy in these countries, might, with seeming justice, expose him to unworthy suspicion that he was performing the play "with the part of HAMLET left out by special desire." The Tories, indeed, of the medical corporations have already had the sagacious malignity to turn to their purpose this construction of the occurrence; they have been busy all the week in balancing the unjustifiable inference from a mere accident, against their own candid and avowed advocacy of these abuses. Mr. ELLIS will, we have no doubt, on some future occasion, see the necessity of putting these cavils to rest. He may also fairly take the same opportunity of reconsidering certain opinions in his discourse, in which other medical practitioners certainly cannot concur. In speaking, for example, of hospital appointments derived by "purchase" and "descent," our report of his lecture describes him to have said that the persons who are concerned in the support of this infamous traffic and practice, are warranted in their proceedings. Making every allowance for the intention of condemning the crime and saving the transgressor, which we consider to have been the object of Mr. ELLIS in this nice discrimination, it is unquestionably true, that no man has a right to enter into a compact which will be productive of detriment to the public welfare. Within that class of evils falls every treaty to purchase a permission to kill or cure the inmates of an hospital, with liberty again to "sell out" to a successor. This power constitutes nothing less than the justification of one evil by the existence of another,—making vice and immorality permanent by precedent,—nay, conferring on both an abstract existence, and liberating their author from the trammels of responsibility! This, to be sure, may be good law in the hospital market, and a consoling enactment it must be to purchasers in that arena of bargain and

sale; but the reflection of a moment must convince Mr. ELLIS that the doctrine is incompatible with the received standards of morals and justice. If such a system of "ethics" is to be defended, let the labour be performed by those who practise and profit by it. Reformers surely are not called upon to burden their case with the palliation of abuses, for the removal of which they may be pledged by the elevation of their name and their principles. If the abettors of this system be given "an inch," they will instantly take "an ell;" and instead of being conciliated by the concession, the first act of their gratitude will be to convert the charitable boon into a new weapon of aggression. Upon this single admission, we have no doubt, for instance, that Mr. CUSACK would undertake to produce a plausible vindication of every appointment which has been made in *St. Stephen's Hospital*, from the hour of its foundation down to the installation of WILLIAM COLLIER by ABRAHAM, his father,—that he would engage to satisfy the greatest sceptic in mis-government that the promotion of three apprentices, by Mr. CRAMPTON, to surgeoncies in the *Meath Hospital*, was perfectly consonant with the ordinances of reason; and that even the payment of two hundred pounds by Dr. GRAVES to Dr. HARKAN for the situation of physician to the same establishment, was most virtuously made. Neither Mr. ELLIS, nor any other reformer, would, we presume, wish to be quoted as an authority by Mr. CUSACK, in the establishment of such conclusions as these, even though Mr. ELLIS and his coadjutors in reform could look upon the act as "the devil citing Scripture to suit his own purposes." In the question now at issue between these parties, the line of demarcation is on every point sufficiently defined to guard the reformer against mistakes of description. It is to prevent the description of such errors, that we here point for comment, and otherwise contained

MISFEITINGS have become the complaints relative to the "new arrangements" for providing medical attendance under the Poor-law Amendment Act. The letters which we continue to receive on the subject are nearly all directed against the conduct of the Commissioners who are sitting at Somerset House. In this wholesale condemnation of those gentlemen there is manifested very considerable thoughtlessness, and no inconsiderable portion of injustice. In the last session of Parliament it was distinctly stated by Lord JOHN RUSSELL, Secretary of State for the Home Department, that the subject of providing medical attendance for the sick-poor, should receive the immediate consideration of the commissioners, and, very soon afterwards, Mr. HODGES, the Member for Kent, and a deputation of medical gentlemen from that county, were informed by Mr. FRANKLAND LEWIS and his colleagues, that the Boards of Guardians in the respective parishes, had full power to contract with as many medical men as they thought proper, and on such terms as they might consider that the interests of the poor demanded, in the parishes in which the Boards exercised their functions. On whom, therefore, ought the censure to be thrown, if the contracts are characterized by a disregard for the interests of the poor and the welfare of the profession? Obviously not on the Commissioners, but on those rate-payers who have been elected to constitute the Boards of Guardians. Instead, therefore, of attempting to prove that the conduct of the Commissioners, relative to the medical contracts, is tainted by traits of odious cruelty, it would be well if the writers and observers who are so generously exerting themselves in the rural districts, would attempt to infuse into the Boards of Guardians, some feelings of humanity towards the poor. The names and addresses of the members of the Boards of Guardians who have made some of the infamous contracts which have been so justly condemned, should be forwarded to us for publication. Until, however, it can be proved that the pledge which was given by the Commissioners to Mr. HODGES has been broken, no action can be taken. As made by Lord JOHN

RUSSELL have been falsified, public indignation, instead of being directed towards the Home Office and Somerset House, ought to fall, with undiminished weight and severity, against the merciless Boards of Guardians who have attempted wilfully to sacrifice the poor, by withholding from the wretched sufferers, efficient medical skill, and even necessary medicine, in the hour of sickness.

It must be admitted by every impartial person, that in carrying the new law into operation, the Poor-law Commissioners are placed in extreme difficulty. The Poor-law Amendment Act is an unpopular measure, —in our opinion most justly so, as we certainly consider it to be one of the most harsh enactments that ever received the sanction of a British Legislature. It is next to impossible, therefore, that those gentlemen can take a step, in any direction, without giving offence to a large portion of the community. It will be recollected that one great complaint against the new law was, that the power of managing their own funds was transferred from the rate-payers to the nominees of the executive Government. The objection was founded in truth, and it was correctly and constitutionally urged. But the Commissioners, in relation to the medical contracts, have entirely obviated such an objection by allowing the Boards of Guardians to make their own contracts for medical attendants. The authority is in the hands of the rate-payers or their elected representatives. Had the Commissioners exercised their full power, and taken the privilege of making medical contracts, from the rate-payers or the Boards of Guardians, then the *despotism* of their conduct would have been denounced. Really we are bound to state that so far as the Poor-law Commissioners are concerned, the subject of providing medical attendance for the poor in the newly-created Unions, has been discussed with much perverseness of judgment, and, in some cases, accompanied by evident signs of factious malignancy.

As the experience of one year has made it but too apparent that the Boards of Guardians cannot be safely entrusted with the medical care of the sick poor, the Poor-law Commissioners could not be censured if they were, henceforth, in all new contracts, to withhold the management of that department from those bodies, and retain over it their own uncontrolled authority. Though

the saving of a few pounds in the pockets of the Boards of Guardians may induce them to make disgraceful and brutal contracts with low-minded medical adventurers, the Poor-law Commissioners sitting in Somerset House cannot possibly be influenced in their conduct by any such unworthy and sordid motives. The interests of those gentlemen are of a totally different character.

ANOTHER article by Mr. RADLEY, on the treatment of fractures of the bones, without the employment of splints or tight bandages, will be found at page 288. The subject is one of deep and pressing importance, as we are given to understand by Mr. RADLEY that the non-application of splints to fractured limbs is attended with an inconceivable degree of ease to the victims of the accident. When, therefore, it is borne in mind that the great object of cultivating the science of medicine is, in every instance of disease, to diminish the measure of human suffering, nothing but prejudices of the most odious character can prevent the system practised for so many years by Mr. RADLEY, from being brought into immediate operation in our public hospitals. In again adverting to this interesting subject, we ought, in justice to that distinguished surgeon Mr. WARDROP, to place before our readers the following sentences from a clinical lecture which was delivered by that gentleman and published in *THE LANCET* of Oct. the 4th, 1834, page 55:—

"The subsequent cases are intended to show that splints, bandages, and the complicated mechanical contrivances usually employed in the treatment of fractures of the thigh-bone, are not necessary in all cases, and may sometimes be altogether dispensed with."

"The injurious effects which are produced by the use of splints and bandages in the treatment of fractured bones may frequently be observed, and I am convinced that in many cases and under many circumstances they may be well dispensed with."

"While splints may no doubt be often employed, at least without mischief, there are, on the other hand, cases wherein they are decidedly hurtful; I allude to those in which the soft parts adjacent to the fracture are so injured or bruised that the pressure of bandages or other apparatus becomes a source of irritation, and thus creates more or less inflammation, which, instead of promoting the reunion of the fractured bone,

retards that process, and I have known extensive suppuration take place in the soft parts, even from this cause alone.

"In fractures of the lower limbs I would therefore strongly urge surgeons to consider in what cases or under what circumstances splints and bandages are requisite,—in what cases they are hurtful,—and when their application is nugatory. If they are not decidedly necessary, or *considered* improper, it is of great importance to attend to the kind of bed on which patients with fracture are to be placed, taking especial care that it is one plane surface, . . .

placing a dossil of tow to fill up any inequalities, such as that in the ham or at the heel, preventing the smallest exertion or muscular action being made by the patient to support the limb, and thus allowing the fractured member to be in a perfectly quiescent state.

"This simple mode of managing a fractured limb has also the advantage of admitting the ready employment of leeches, or such other local applications as may be requisite to subdue any inflammation at the seat of injury."

THE Council of the *University of London*, on the requisition of a numerous body of the proprietors of that institution, have appointed a meeting of the shareholders, to be held in the first week in the ensuing month. The chief subject to be considered by the meeting is, the charter, which, it is understood, the Crown is willing to confer, with certain restrictions in the conditions. As we take a very deep interest, on purely public and national grounds, in the continued success of the University, we shall look forward to the proceedings at this meeting with considerable anxiety, and not without some degree of apprehension. The institution, so far as the medical department is concerned, has become so firmly established, and has taken so bold and successful a stand,—far out-topping, in celebrity, every one of the "recognised" establishments connected with our endowed hospitals,—that it is now clearly evident that no charter, or extrinsic aid of any kind, can increase the utility, or add to the reputation, of the University medical school. The best security for the continued prosperity of at least this branch of the establishment, may be found in the talents and industry of its professors.

In the next *LANCET* we shall propose the proposed object of length,

AGREEABLE NEWS FOR PRACTITIONERS IN THE COUNTRY.—"The Marchioness of Londonderry, who is in a delicate state of health, will, it is expected, shortly visit the metropolis for the benefit of more skilful medical advice."—*Sunderland Herald*, November 14.

It is really surprising that the intelligent conductors of respectable country journals should introduce such trashy paragraphs into their columns. There is scarcely a town in England which does not contain practitioners in medicine who are equal in ability to those who are styled "first-rate practitioners" in the metropolis. When operations are requisite, we admit that the patient is safest in the hands of that surgeon who is frequently called upon to use those appropriate of medical practice, steel instruments; but in cases which require no such aid, the sufferers would act wisely in not relinquishing, on slight grounds, the pure air of the country.

ROYAL MEDICO-CHIRURGICAL SOCIETY.

Tuesday, November 10th, 1845.

MR. EARLE, PRESIDENT.

MORBID VASCULARITY OF PARTS.

THIS Society commenced its first medical course for the winter this evening, and was numerously attended.

Attention, at the opening of the proceedings, was directed by Dr. J. YELLOLY to the subject of the vascularity of mucous and serous membranes. The author in his communication,—and in this consisted its substance—considered that the presentation of a vascular appearance in any part, from disease, does not always indicate the existence of inflammation, as reddened appearances might exist, without the existence of inflammation. On this division of the subject Dr. YELLOLY considers that pathologists of the day have yet much to learn before they can positively affirm whether the change is a result of the process of inflammation or not. According to present notions on the subject, he observed, this vascular or reddened appearance is oftentimes pronounced to be inflammatory, when that process has never existed in the part. In proof of the assertion, and in order to shew the fallacy of appearances, the Doctor exhibited a drawing of a portion of spinal marrow, apparently vascular, but in which the vascularity was not on inflammation, but on a state of *turgescence*; proving, as the subject still required minute examination, that the mere display of vascularity, the

Doctor recommends that due attention should be paid to the position of the body, because vascular fulness in the dead subject is exceedingly delusive; and there will, moreover, be found various degrees of vascularity, which, as in the example presented, are simple cases of *turgescence*.

Dr. WEATHERHEAD considered that this important topic ought not to be allowed to pass by in silence. That a *turgescence* of vessels was not a sign of inflammation, he readily admitted. But the difficulty was first, how is the effect to be explained? and secondly, how were the true and unequivocal signs of inflammation to be described? How, for instance, came blood to be accumulated so largely in the heart, when the bloodvessels are themselves, comparatively speaking, empty? Did not the circumstance prove that the vessels had the power of propelling the blood onwards, after the heart had ceased to beat? He therefore regarded the *turgescence* of vessels in mucous tissues, to arise from the weakened state of the vessels, situated as they were remotely from the centre of the circulation, as compared with those vessels which were more advantageously situated for propelling the blood onwards.

Dr. CLENDINNING agreed with Dr. J. YELLOLY, that the *turgescence* of vessels in most instances occurred simply from the position of the body, and in such case must not be regarded as proofs of inflammation, having existed in those parts. He had seen, at various inquiries, this state of the vessels adduced as a sign of inflammation, the verdicts being founded accordingly. His object in rising, however, was simply to prevent the discussion from dropping.

Mr. ARNOTT, on the other hand, at once rose to prevent its continuance, for as it seemed that the profession knew not what inflammation was, but judged of it only by its external characters,—heat, redness, swelling, and pain,—he could not consider that the paper which had been read tended to communicate or elicit anything sufficiently exact to make it worth while to debate the matter. The paper certainly did not say what inflammation was, and until all agreed as to what it consisted of, it would often be found impossible to account for post-mortem appearances, whether they were inflammatory or not; and most practitioners must have observed that a redness was frequently seen to exist in a part antecedent to death, after which it disappeared, leaving no detectable morbid change.

Mr. MAYO could not agree with Mr. Arnett in his view of the discussion. Although occasionally no traces were left after death, when redness had previously existed, yet if such inquiries as these were not prosecuted, how were the profession to discover or know of what inflammation consisted?

Here the subject was dropped.

TUMOUR OF THE SCAPULA.

The Secretary (Mr. Partridge) then read a report of a case in which a large tumour was removed from the scapula by Mr. EARLE, some account of which was reported in *THE LANCET* lately.

The details of the case ran thus in Mr. Earle's paper:—James Jackson, admitted September 10th, 1835, into *St. Bartholomew's Hospital*, suffering from a tumour of the left scapula. Thirteen months ago his attention was called to the seat of affection, by pain which extended down the arm of the same side, and went on increasing up to the time of his admittance, when the tumour had grown to the size of an ostrich egg. It partook of every motion of the scapula, and was evidently in close contact with the bone. The man's aspect was bloated and unhealthy, and he had been a free liver. Leeches were applied and the arm was supported in a sling. Several consultations were held, as to the propriety of removing the tumour with the knife, but unfavourable opinions of the case were formed, and it was deemed not advisable to operate, from the probable malignancy of the tumour. Mr. Earle, however, was of a different opinion, which he founded on the perfectly healthy condition of the integuments covering and surrounding the mass. The serratus major action, and its several digitations were easily traced, and between that muscle and the under surface of the scapula the tumour was situated. The patient was willing to undergo any operation rather than its removal should not be effected. The operation was performed on the 3rd of October, but it was undertaken with the understanding, that if found necessary, the scapula should be taken away also. In the course of the operation, the tumour was found adhering firmly to the inferior angle of the bone; but the remainder of the tumour was easily detached from the surrounding parts. A small portion only of the bone was absorbed, and only a small spicula of bone was found necessary to be taken away with the forceps. Two arteries were tied. After the removal a compress and bandage were applied, and during the progress of the cure, not a single unfavourable symptom had arisen. The man left the hospital, on November the 14th, and had since regained the use of the arm very satisfactorily. The case, therefore, went on to say, was valuable in a practical point of view, and proved the advantage of forming a diagnosis on anatomical appearances. The tumour presented a specimen of albuminous sarcoma.

After the report had been read, Mr. Earle said he had brought it forward, because Mr. Partridge had informed him that there was a paucity of papers, but he trusted that a regular succession would be supplied, so as to be able to continue the "*Transactions*," the keeping up of which constituted the

pride of the Society. At the commencement of the sessions, invariably a paucity of subjects was complained of, but at the termination an influx was received, compelling the Society to call an additional meeting. He, however, had to congratulate the members on its present flourishing auspices, for no session before had presented so many highly respectable names of gentlemen who were desirous of becoming fellows of the Society. Finally, the President alluded to the expenses incurred "in moving the House of Commons" in order to obtain the charter. These had threatened to become a serious inconvenience, but they had since been liquidated, and prosperity now reigned in the treasury.

LONDON MEDICAL SOCIETY.

Monday, Nov. 9, 1835.

Dr. WUTTING in the Chair.

CHIMNEY-SWEEPERS' CANCER.

Mr. HENNER introduced the subject of chimney-sweepers' cancer, and related the following case of a patient aged thirty-five years, who was in *God's Hospital* for the above disease about eighteen months ago, when the wound presented a surface of the size of a five-shilling piece, which was operated on, and had yet to do well, but the man left the hospital before it was quite healed. Twelve months since he (Mr. H.) was consulted, the wound had again assumed a serious aspect, and went on increasing, and the patient, fearing the effects of a second operation, neglected to apply for relief; and from the incapacity of following his employment, he became reduced to a state of almost actual starvation. The disease had commenced in the scrotum, and extended up to the groin. The left arm (particularly) and the left leg were now oedematous; the pulse 120 and feeble; and the man was evidently sinking, from the exhausted state to which he had suffered himself to become reduced. He was a fortnight in the workhouse, but nourishment was then too late, and this morning he died. He (Mr. H.) considered the case to well illustrate the proposition laid down by Mr. Abernethy, that cancer will invade any structure of the body; for on examining the tibia in this case it would be seen to be affected with exostosis, although the patient had made no complaint of his suffering in that part. On inspection of the body, no other disease was detected in any of the organs. A small quantity of fluid was found on the inside of the chest; the liver was enlarged, as in most persons of the same age, and they themselves up as this.

he could get it, to the temptation of drink.

Mr. CRISP inquired if the members had found the disease invariably to return after operation, for he had heard Mr. Travers remark that it invariably reappeared.

Mr. JONES did not regard the disease of the tibia cancer, but rather as the effect of soot taken into the system. Was the disease in the present case simply local or constitutional?

Mr. HOOPER said, that this man was perfectly free from other disease in all the viscera; but in other kinds of carcinoma, the glands of the body were found affected. Proper nourishment last year would have prevented his life from being shortened by the disease. The pains were lancinating, and attended with a burning heat over the surface of the wound.

Mr. DENBY thought that had the man lived longer, the disease would have produced greater ravages in the system. He thought that some modifications of the disease might occur in all parts of the body. How far soot could effect a change in the bones he knew not, but he could not believe that its absorption had caused disease there.

A GENTLEMAN, whose name we could not learn, regarded the disease as local, but capable of being easily excited. This gentleman was led to relate a case of hemorrhage in a chimney-sweeper from the stomach, to the extent of seven pints, which proved fatal after a second attack, when the stomach was found converted into a diseased mass weighing sixteen pounds. A second case was related, which consisted of a small spot by the side of the penis. The patient consulted Sir A. Cooper and Mr. Abernethy, who recommended its removal, but Mr. Abernethy observed, as it was a portion of malignant tumour, that sooner or later the circulation would become affected. The penis was removed, but the patient died. The disease was supposed to have been brought on through the irritation caused by riding on horse-back.

Mr. JONES, after making a section of the bony preparation belonging to the man who died from cancer, still maintained that it did not represent simple exostosis; for the particles arising from the deposition of fibrin, radiated from a centre, like the bones of the skull in the fetal state; it presented also a cellular structure, and the marrow was contained not in the regular canal of the bone, but in distinct cysts.

Mr. BRYANT asked whether Mr. Jones would not have considered it a case of exostosis, if it had been unconnected with the chimney-sweepers' cancer.

He replied, certainly not, but

 taken from the body was
presented the characteristic
disease.

rather medullary sarcoma affecting the bone.

Dr. THOMPSON argued that it depended in great measures as to the soot becoming absorbed and affecting the system, whether a tendency in the constitution predisposed to carcinomatous affection. In ordinary cancerous diseases, it was extremely rare to find the mischief confined to one organ. He believed that diseases of this description required very peculiar care in the management, and in their guidance all sources of irritation should be carefully avoided. In corroboration of his statement, Dr. Thompson related the case of a butcher who appeared well, and led from his avocations an active life. The man left town to visit his friends, and it would seem that from the change to a state of inactivity, a torpor of the bowels followed, which aperients failed to relieve, and the man died. On inspection of the body, a tumour, decidedly of a scirrhus nature, was found at the termination of the colon. The caliber of the intestine did not exceed the diameter of a quill. The disease was not developed in any other organ, therefore he was led to the conclusion, that if the necessity of having recourse to the aperients had not been compulsory, and produced irritation on the immediate seat of the disease, the part would have remained quiescent, and the patient's life been prolonged. The Doctor related a second case in support of his position, that of a man aged fifty years, who felt tolerably well, but suffered from vomiting, which led him Dr. T. to treat the disease as a chronic affection of the stomach. Becoming, shortly after, more fully acquainted with his sufferings, he (Dr. T.) was led to conclude that it was of a cancerous nature; and on examining more carefully with this impression, he found several tumours about the size of a pea, adhering to the skin of the arm and scalp. Attempts to allay the vomiting failed, but afterwards it ceased spontaneously, and the patient became more fleshy, and he concluded that he should get well. About one month after, he rose from his bed to micturate, then suffering from irritable bladder, and fell down dead. At the autopsy every viscera of the body was found studded with tumours, similar to those on the external surface of the skin, and an effusion of fluid was seen in one of the ventricles of the brain.

Mr. DENBY believed, that if the records of hospital reports were consulted, they would tell us that almost in every instance the disease returned again, after the operation for cancer was performed. He did not look upon soot as a common irritant, for it failed to produce the disease in many parts of the system.

TUBERCULATED DISEASE OF THE UTERUS.

Mr. BRYANT rose to give the particulars

of a preparation which he had placed on the table. The individual from whom the morbid parts had been taken, had not fallen under his care. The subject of the case, a lady, unmarried, aged fifty-two years, was of short stature and spare habit, and had for some years suffered from indigestion, accompanied with headache and sluggishness of the bowels. About three years since, she became "irregular," and about eighteen months ago the catamenia ceased altogether. She was next troubled with vomiting, about half an hour after taking any food; a hardness was felt on the right side, and she became emaciated. Latterly, she suffered from forcing pains, after evacuating the bowels, but no symptoms of uterine disease existed. The evacuation gradually increased, diarrhoea followed, and she died on the 30th of October last. Several weeks previous to her death the irritability of the stomach ceased, and she was able to retain her food, but was distressed by flatulence, and pain in the bowels. On examination of the body, the heart was found to be exceedingly small, with its vessels enlarged in caliber. The gall-bladder was distended with a cream-coloured bile, and its coats very much thickened; in the ductus communis choledochus a calculus was impacted, weighing five grains; when dried it was of a bright colour, with a tuberculated surface. The uterus had undergone the change observed in the preparation, but this change was not suspected, as the attention of the medical gentleman Mr. Hiff, was not directed to it by the patient. The case was interesting, from its adding confirmation on an important topic, that a disease of a formidable nature might go on even to the destruction of life without being suspected, and in which no symptoms are manifested, either to lead to a detection of the disease, or suspicion of its existence.

The PRESIDENT asked whether the thickening of the pyloric orifice of the stomach, was of a cancerous nature.

Mr. BRYANT replied, that Mr. Hiff's opinion led him to that conclusion, although the thickening was not great.

Mr. MOORE was opposed to the opinion that the disease was of a tuberculated nature; he regarded it as rather of a scrofulous kind, and his judgment was supported by the accounts of the French pathologists. M. Louis had recorded, that of upwards of 300 cases of disease of the womb, only one of tuberculated disease of the uterus existed. He (Mr. M.) was led to this conclusion from the nature of the inflammation (not having examined the preparation very circumspectly), which was of a chronic kind, and unattended with pain.

Mr. CRISP thought that the time of the Society might be spent more profitably, by considering the relief of patients at the early

stage of the disease; and he would ask, whether the experience of the members led them to conclude that anything could be done in such cases, or whether they had found beneficial results from the use of iodine, from pressure, or from counter-irritation.

A GENTLEMAN said, with regard to cancerous affections of the breast, that he could inform the Society that in a case within his knowledge, where iodine had been applied, it had increased the tumour in a very short period to double the size it presented when the iodine was first used.

Mr. MOORE, in order to counterbalance the last case, briefly alluded to one in which iodine, combined with mercury, and so softened down as not to produce irritation of the skin, decidedly lessened the activity of the disease, and kept it under control.

Dr. JOHNSON believed that the profession knew but very little about these diseases; but he felt convinced that it might be retarded by taking from the part affected the supply of nutrition as much as possible; abstracting blood from it—that being the pabulum of life, applying leeches, allaying pain by emollient and soothing fomentations, and avoiding irritants, for "ubi stimulus, ergo fluxus," and keeping the excretions and secretions of the body in the best possible condition.

The PRESIDENT, previous to the adjournment, requested to relate the following case:—A lady, who was extremely pallid, and labouring under all the characteristic symptoms of a severe constitutional disease, was suddenly attacked with suppression of urine, which was found to arise from the mouth of the womb pressing forward, so as to prevent the urine from flowing. The uterus was tilted back by the practitioner, and a catheter was introduced to draw off the accumulated fluid. The neck of the uterus was found hardened and callous, indicating a scirrhus affection. Repeated discharges of blood occurred from the uterus, and pressure gave considerable uneasiness. The lady was ordered to remain in bed, to have leeches applied, the accumulation of urine to be prevented, and to take bland food. On a second visit, he (Dr. Whiting) found her suffering from more acute symptoms; the tumour had increased, and become exquisitely sensitive to the touch, and the patient was labouring under irritative fever. A second application of leeches was directed, and the following week found her infinitely better, and the tumour subsiding rapidly; but it was deemed advisable to continue applying leeches until all the symptoms had abated. Iodine was rubbed in over the abdomen, and he (Dr. W.) thought that the gentleman who attended the case had applied it to the mouth of the uterus. At present the lady was so much better that further professional aid was deemed unnecessary.

Monday, November 1834.

At the close of the meeting the chairman stated, that a complimentary address had been drawn up by some gentlemen of the profession (not confined to the Society), assisted by Mr. Headland, the secretary of the Society, which it was intended should be presented to Mr. Kingdon, after it had been signed by as many members of the medical profession as accorded with the originators, that his conduct had not in the slightest degree merited the stigma cast on it by the Council of the College of Surgeons; for this reflection, as Mr. K. professed it to be, on his moral conduct, preyed most heavily on his mind, and fit we understood the statement correctly, not only caused the discontinuance of his attendance at the meetings of the Society, but also everywhere else from home.

When Mr. Kingdon informed the Society of "the disgrace" as he termed it, under which he laboured, from his rejection by the Council, he said that the heaviest affliction that he felt arose from the fact that what he had most attempted to preach to his children, — the propriety of preserving their moral characters unimpeachable, — he himself, it would seem, had not been able to accomplish in his own person. On that occasion Dr. JOHNSON remarked that there was no necessity, so far as his conscience was concerned, for Mr. Kingdon to feel hurt at being passed over by the Council, for he might be assured that in the eyes of the profession he would not stand degraded one iota, probably the reverse; for the proceedings of the Council in Lincoln's Inn Fields had long ceased to be regarded with respect by medical men.

A veto, however, was placed on the address being left in the rooms for signatures, in consequence of a remark from Mr. LEVER, that although the members might firmly and conscientiously coincide with the motives which had actuated the gentlemen in drawing up the document, yet he for one (and this he said from a very long acquaintance with Mr. Kingdon) could not put his name to a paper that conveyed, even indirectly, and although denied to the public, a suspicion that moral delinquency had ever hung over Mr. Kingdon's character. This he considered the address was calculated to do, and most of these present acquiesced in the opinion. It was deemed advisable that certain of the sentences should be erased, and a new copy produced and offered for signature. Although these brief proceedings took place in the library of the Society, it was not wished that the address should be

considered as emanating solely from the chairman's object in bringing it forward. Mr. LEVER arose, he said, from the fact that many members would be

WESTMINSTER MEDICAL SOCIETY.

Saturday, Oct. 31, 1835.

Mr. R. QUAIN, President.

THE newly-elected President, Mr. Richard Quain, in conformity with the example set by his predecessors in the chair, this evening addressed the Society in an inaugural speech. He thanked the members for the honour they had conferred on him; but at the same time a retrospective view of their past presidents, and many able members, almost induced him to shrink from the responsibility of office, though no member felt more anxious for the welfare of the Society, than he. Of its usefulness there could be no question. For himself he could say that he had never entered its walls without deriving benefit from the discussions. The arduous duties that he had elsewhere to fulfil, would, he trusted, become an apology for any imperfect fulfilment of his duties in the Society, which at any rate, however, he would endeavour to perform with the strictest impartiality. The Society had this session to lament the loss of one of its most zealous and able members. It was not his intention to offer any *éloge* on the late Mr. BERNETT, as ample justice had already been done to his memory. (These notes necessarily form but a very brief outline of the address of the worthy President.)

The discussions this evening commenced by Dr. LEONARD STEWART inquiring whether Dr. JOHNSON had received any further particulars of the case see LANCET, No. 634, lately forwarded to him (Dr. J.) for his opinion, and detailed to the Society.

Dr. JOHNSON answered in the negative. He had written to the parties, and embodied in the correspondence the opinions of the Society. Not that he expected to hear very soon, as it was a case not likely to be cured expeditiously, if at all.

ANTIMONY IN PNEUMONIA.

Dr. ADDISON requested the sense of the Society respecting the efficacy of the antimonial treatment in pneumonia.

Dr. JOHNSON considered Dr. Addison, as an hospital physician, best calculated to give an opinion on this treatment. In pulmonic inflammation, he (Dr. J.) had pushed the antimonial treatment further than in any other inflammation, but would not trust exclusively to it. The use of the lancet he regarded as highly necessary and beneficial in weakening the action of the heart and arteries in inflammations.

Dr. ADDISON replied that he did not allude to antimony, when used in combination with other remedies; for, in the ordinary use of antimony, calomel and opium generally were combined, and not unfrequently

preceded by the use of the lancet. But the treatment that he resorted to, was the trusting to large doses of antimony to the exclusion of other remedies. He (Dr. A.) was induced more particularly to give it a trial, from having seen in a severe case of laryngæa, which he had been requested to visit in company with a general practitioner, great benefit derived from the treatment, and he was unwilling to interfere with the remedy that was producing such beneficial results. It was persevered in, and it quickly effected a speedy and complete cure. What he (Dr. A.) looked upon as constituting the antimonial treatment, consisted in administering from half a grain to a grain of tartaræmic in solution every one or two hours. The first and second doses probably produced vomiting, followed by nausea and free diaphoresis; and he would ask whether we were not justified in abstaining from so harsh a remedy as mercury, and adopting antimonial treatment in preference, at least in the milder forms of inflammatory disease. Of late he had had reasons to doubt whether pneumonia was so severe as it was formerly taught to be. They used to be led to believe that it was a most serious and fatal disease, seldom admitting of cure. Cases had occurred within the last few years which had led him to doubt the correctness of this proposition, and many cases had come under his observation, where the disease had been altogether overlooked. He certainly thought that large bleedings, in the majority of cases, were injurious, and smaller bleedings as by far more safe and more appropriate.

Mr. COSTELLO said that the Italian school was certainly in favour of the antimonial treatment, and that the rate of mortality under its use was not more than one in eight cases. This calculation was made from cases of the serious kind, and after moderate bleedings had been used.

Mr. H. JOHNSON remarked, that during the time he was at St. George's Hospital, several cases of pneumonia were admitted, in which the antimonial treatment had received a fair trial; but from the result, it was considered to be an inefficient remedy. If a preference was to be given by him, he would choose the mercurial. He did not think that the French surgeons were well acquainted with the use of mercury, for even Andral was only now beginning to regard mercury as a powerful remedy. He differed from Dr. Addison as to the mildness of pneumonia. He (Mr. J.) had found it any thing rather than a mild form of disease in the surgical wards of St. George's.

Dr. JOHNSON remarked that in 1812, an ample opportunity was afforded for experimenting on pneumonia in the Scheldt, when that disease attacked almost every individual there stationed, and the medical officers employed under government on

that occasion, found that opium disadvantageously checked the expectoration; and that by first bleeding the patients, as much as their strength would admit, and then exhibiting calomel, only in sufficient doses to act on the secretions, more benefit was obtained than by any other kind of treatment.

Dr. ADDISON still maintained that pneumonia was not so fatal as was generally conceived. He thought that Mr. Johnson was particularly unfortunate in selecting cases from the surgical wards of an hospital, to illustrate cases of genuine idiopathic pneumonia, for he (Dr. A.) was not a stranger to that division of our public institutions. There pneumonia would either be found occurring with other diseases or in broken down constitutions. He (Dr. A.) was sure Dr. Johnson would excuse him when he said that pneumonia did not terminate in expectoration,* unless complicated with bronchitis, and he very much doubted, whether the majority of these cases were not cases of bronchitis, instead of pure pneumonia.

Mr. JOHNSON could not regard pneumonia as a mild disease. He had always found that the more actively it was treated, the fewer were the deaths. As to pneumonia in hospitals, the fact was that pneumonia could not be explained by a few cases, and the patients that he had selected from the surgical wards were, many of them, in rude health, who had been overtaken by some untoward accident.

Mr. WARR said, with regard to the treatment of pneumonia, according to the mode of exhibition recommended by Laennec, he

Mr. W. had found, that if the inflammation was first attacked by a full bleeding, so as nearly to produce syncope, and then followed up by large doses of antimony, the latter had proved a most valuable remedy in his practice. With regard to a remark which had been incidentally made, that all adhesions of the pleura were not the result of inflammation, he would give an example in proof of the allegation, that had made at the time considerable impression on his mind. A portion of the lung recently taken from the body was brought to him, which he divided into two portions, and then placed their cut surfaces in opposition. On the following morning a perfect adhesion was found to have taken place, and the lymph through which the adhesive process was maintained, presented, from evaporation of the serum, the same phenomena in

* It may be necessary to state—as the abridgement of the proceedings to the proper compass of the paper does not make this isolated point obvious—that Dr. Johnson assigns expectoration as a symptom of pneumonia, which Dr. Addison does not. He also mentions that the termination of that affection when complicated with bronchitis, is a case. Dr. Johnson considers that the expectoration is up by nature to unload the lungs, and is a sign of the disease.

appearance as were produced by the known process of inflammation.

Mr. SMITH believed that pneumonia attacked two kinds of constitutions, the strong and the delicate, and he presumed that the mercurial was best adapted for the plethoric, and the antimonial for the weak. The President then adjourned the meeting.

(Saturday, November 7—Concluded.)

REMARKABLE DISEASE OF THE BRAIN AFFECTING THE SENSE OF SIGHT.

After the statements had been made respecting the late Sir David Barry, which were reported at page 264,

Dr. JOHNSON communicated a paper which was entitled "A remarkable Disease of the Brain, attended with distressing symptoms." The subject of the case was an eminent artist residing in Albemarle-street. The complaint commenced several years ago, in the form of a sensation of flashes of light before the eyes, to which were afterwards added, pains in the head, and the sight was gradually, and in the end, totally lost. The chief phenomena, however, which annoyed him, was a series of dazzling images, perpetually playing on the optical apparatus, by day and by night, with a brightness unpeckably distressing, sometimes assuming the forms of angels with flaming swords, every motion of which seemed like an electric flash, to blind the eye and sear the brain. The forms and colours of these spectral illusions were incessantly changing, but without any mitigation of the sufferings they produced. With the exception of some irritability of temper, there was not the slightest affection of the intellectual powers. Memory, imagination, and judgment, were unimpaired. He was led about the streets by his servant, and attended to all matters (where sight was not required) with the greatest punctuality. The eyes themselves presented no appearance of disease. These symptoms were ameliorated, from time to time, by tartar emetic plasters to the nape of the neck, leeches to the temples, and aperient and diuretic medicines. In the spring of 1835, he was seized with all the usual symptoms of apoplexy. He lay in bed motionless and insensible, passing the urine and feces involuntarily; the pupils were dilated, and the power of speech was lost; but to the astonishment of his medical attendants, he recovered from this state, whether through the powers of nature or active depletion, was doubtful. After a few weeks he was enabled to go to the city, and transact business. But the spectral images and other symptoms returned with increased violence. In August last he was seized with apoplexy, and died.

As above mentioned, and notwithstanding the same means were employed as for the last attack, he died at the end of three or four days, from the commencement of the apoplectic invasion. The body was examined on the following day. There was nothing unusual in the membranes of the brain. The right lateral ventricle contained nearly two ounces of clear fluid. The left ventricle was occupied by a series of hydatids, of various sizes, and filled with fluid of various consistency and colour. The cluster of hydatids sprung from the floor of the ventricle, by a kind of peduncle, and penetrated into every sinuosity of the cavity, pushing its branches anteriorly, so as to pass over and before the thalamus nervi optici of that side, and even into the opposite hemisphere of the brain, destroying all the parts in its progress. Both thalami were reduced to a pulp, as were, indeed, the whole of the anterior lobes of the brain, which would not bear the least handling without falling into a state of deliquescence. The optic nerves were pressed upon by the hydatid mass, and reduced to little more than the size of threads, and these were of very soft consistence. There was no change in the coats, or the humours, of the eye. The most remarkable phenomenon in this melancholy case, was the intensity of brightness which always accompanied the spectral images. Whatever were their shapes, this dazzling and painful splendour never forsook them. It rendered the life of the sufferer a scene of dreadful agony for some years.

Mr. VERRALL said, he was induced to relate the case of a boy aged 11 years, which he believed was somewhat analogous to the foregoing interesting case. This patient, who he had examined at the *Western Dispensary*, complained of having before him repeated flashes of light. He (Mr. V.) suspected that his faculties were not perfect, as the boy looked stupid, and the questions put to him were invariably answered by his mother; and on further examination he found that the arm was slightly paralytic, and that the fingers were wasted. No change could be detected in the eyes.

Mr. THURNAM requested to know whether the cysts were accidental serous cysts, and what was the condition of the plexus choroides?

Dr. JOHNSON replied that the cysts were filled with fluids of different colours; some of the cysts were circular, the others oval, and all sprung from one root.

The PRESIDENT (Dr. Addison), inquired if there were any somnolency? (The answer was in the negative, except during the apoplectic seizures. At other periods, his faculties were perfectly intact.)

Mr. STREETER.—In the detail of the symptoms, the expression "the only alteration in the intellect that occurred, was an

LOOPLAND ON DELIRIUM WITH TREMOR.

"increased irritability of temper." He (Mr. S.) would ask, does temper belong to the intellect? certainly not; but rather to the disposition!! He (Mr. S.) in the next observation; has a difficulty, as all present are not acquainted with the phrenological division of the brain, of making himself understood; he however considered the case as favourable to the doctrines of phrenology. The disease commenced in the floor of the ventricle, and made its way forwards and upwards, producing softening of the anterior lobes. In the centre of the under surface of these anterior lobes, that portion of the intellectual brain is situated, which distinguishes the form and colour of objects. He believed that it was a well-established fact in pathology, that the inflammation of a nerve heightened its functions; and here the symptoms indicated that the peculiar functions assigned to those parts were greatly disturbed, or greatly exalted, while sight was destroyed, though the eye remained apparently healthy. The whole of the anterior lobes were disorganized without there being any disease of the membranes, and hence it was fair to conclude that the disease had not extended to the cortical structure of the brain, or the membranes would have been involved in the disease. The term "anterior lobe" was itself a vague one, for there was not the faintest line of boundary assigned by anatomists to mark the separation of this division of the brain from the rest, except at its under surface. (Some further remarks, *apropos* to the science of phrenology, were made by Mr. STREETER, but we have not space to give them.)

Dr. JOHNSON said that he was not an anti-phrenologist, but a phrenologist, and he would observe that although the anterior lobes were reduced to a pulpy state, they were yet capable of carrying on their functions. He did not bring the case forward as an argument against the science, but rather that the science might clear away the difficulty which it presented.

The Society then adjourned.

DELIRIUM CUM TREMORE.

To the Editor of THE LANCET.

SIR,—With reference to the note subjoined to Dr. Roots's excellent lecture on *delirium tremens*, just published by you, I wish to state, that I have used the English expression "*delirium with tremor*," and it only, and without the knowledge that the Latin synonyme had been employed by my friend Dr. Elliotson. I do not even now know in which of the journals the lecture, in which this term was used, has been published, otherwise I should have had great pleasure

in referring to it;* for, although I always make references to ~~whenever~~ comes in my way that seems to me deserving of notice I cannot find that I have made any reference to Dr. Elliotson's lecture on this subject. I shall, however, have an opportunity hereafter of doing justice in the matter. The English term, which only I have employed was used in the course of lectures delivered by me during the winter of 1825 and 1826. The name of the complaint is of comparatively little importance; the *pathology*, the *form*, and the *treatment* of it are the topics that most deserve attention. As to these I am entitled to more credit than has been awarded me. I am certainly the first who distinguished two species of the disease. One which I have stated to proceed from inflammatory or excited vascular action in the membranes and periphery of the brain; the other from exhausted nervous power. I am extremely gratified that so able and experienced a physician as Dr. Roots is, has done me the honour of adopting altogether my views as to the pathology and division of this disease, as well as to the treatment founded on both, as both are of the greatest importance in practice. My views were derived from considerable experience, and, since the publication of them, I have seen them confirmed on various occasions. I beg to refer your readers to my article on this complaint; but I may subjoin my division of the complaint, with the *names* and *definitions* I have given of each species. I need not add that the treatment appropriate to each is fully explained.

"I. DELIRIUM WITH TREMOR FROM EXCITED VASCULAR ACTION IN THE MEMBRANES OF THE BRAIN (*Encephalitis Tremefactans* of J. FRANK).

"DEFIN.—With great terror and irritability of temper and violence upon being opposed; a frequent, full, or hard pulse; countenance often wild or flushed, and the head hot.

"II. DELIRIUM WITH TREMOR FROM EXHAUSTED NERVOUS POWER the *True Delirium Tremens* of modern writers, and *D. Traumaticum*, or *D. Nervosum*, DUPUYTREN.

"DEFIN.—With a morbid recurrence of the patient's ideas to his arations; a frequent, weak, or small pulse; cool, humid, or perspiring surface; and loaded, but moist tongue."

I would beg leave further to refer your readers to what I have said respecting intermitte varieties, or modifications of the complaint, and as to its nature, &c. I am, Sir, your obedient servant,

JAMES COOPER.

Bulstrode Street, 16th Nov.

* The passage quoted in THE LANCET, occurred in the lecture by Messrs. Longman.

MEDICAL REFORM ESSAYS.

To the Editor of THE LANCET.

SIR,—After a patient perusal of the various essays forwarded to the Medical Reform Association, the Committee of Examination* have decided that there are not any three deserving of the prizes, although many deserve considerable praise, from the talent and research displayed in them.

It is my duty therefore to inform the essayists that they can obtain their essays by sending a note, with the motto, when any more specific communication that it may be necessary to make, will be made.

I am further directed to communicate the fact that the 100*l.* will still remain in the hands of the Treasurer, Joseph Hume, Esq., M.P., and that the Association will be happy to receive any essays on the question originally propounded, which must be delivered in, on or before the end of December, 1836. Further particulars I shall take the liberty of requesting the insertion of in the pages of your journal in the course of a fortnight or three weeks. I have the honour to remain, Sir, your obedient servant,

JOHN ERS, M.D.,

Hon. Sec. to the Med. Reform Assoc.

89, Great Russell-street,
Nov. 17, 1835.

CLINICAL LECTURES IN LONDON.—To the Editor.—Sir,—It is stated in your Number for November 7, that 12 years ago there was not a clinical lecture given in London. As regards the *Hospitals*, to which the statement appears to refer, this may be correct; but as the fact is not stated with such limitation, I beg to observe that Clinical Surgical Lectures were given regularly at the Finsbury Dispensary by myself in the October of 1821, subsequently to my election in the preceding April, and these were I believe the first clinical lectures delivered in London. Leaving it to you to make any use of this note you may think proper, I remain, Sir, your obedient servant.

GEORGE MACILWAIN.

Argyll-place, Nov. 17, 1835.

IODINE IN DIABETES MELLITUS.—To the Editor.—Sir,—The perusal in your excellent journal, of a paper on the discovery of sugar in the blood of a diabetic patient, induced me to forward to you a note, a case which I have treated successfully with iodine. The patient, a young

man, of about twenty years of age, had laboured under diabetes mellitus for upwards of two years, and had taken successively the mineral acid, tinct. ferri mur., et potassae sulphas, but without effect. In the month of May last I commenced exhibiting iodine, in the different forms of the ioduret of iron, and of potassa, and, lastly, in the form of tincture. Shortly after the commencement of this treatment a good deal of expectoration took place, and mucus was thrown up regularly every morning. By degrees the urgency of the case subsided, and now, although the weather has become cold, very little tendency to diabetes remains. I hope that others may try the effects of this drug in this generally uncontrollable complaint, and watch its action and result. I remain, Sir, your obedient servant,

C. A. D.

Goswell-street-road, Nov. 17, 1835.

* * Our correspondent should have added his name.

DISTRIBUTION OF SUBJECTS.—To the Editor.—Sir,—I shall feel obliged if some explanation is given in the next Number of your valuable periodical, of the cause of the present very unequal distribution of subjects for dissection; one of the west-end schools having as many, or more than they can dissect, whilst in the Borough we can get very few indeed, bearing no comparison to the demand, and proving a very serious inconvenience to the students in general.

I am, Sir, your constant reader,

A WEBB-STREET PUPIL.

Nov. 16, 1835.

* * We much doubt if the "distribution" is unequal. Does our correspondent know the proportions on authentic information?

To the Editor.—Sir,—I throw myself on your justice, in transmitting the following reply to an article in a late Number of THE LANCET, Aug. 29, on the subject of "Dr. Wright's Pearl Ointment for Cutaneous Diseases," of which I am (by purchase) the proprietor. The writer of the article, without qualifying doubt, asserts that the active principles of this ointment are arsenic and bichloride of mercury,—yet it does not contain an atom of either of those substances! It is not surely too much, therefore, to expect that his pathological deductions are equally fallacious; and that the symptoms, which he describes as having succeeded to the use of the ointment, had no reference, in the connection of cause and effect, with the application. The writer of course is too honourable a man to ascribe effects to this ointment which he does not conscientiously

Committee of Examination
if they are not already

tiously believe to have resulted from its use, or which he knows were produced by other treatment; he is evidently a man "who bears his faculties so meekly," that he is wont rather to extenuate faults than "set down aught in malice." * * * I am, Sir, yours respectfully,

ZACCHEUS HUNTER.

Webber Row, Blackfriars, Oct. 24, 1835.

* * No attack having been made by our correspondent, "A Licentiate," on the character of the late Dr. Wright of Stafford, we have omitted the concluding portion of Mr. Hunter's letter, thinking that it was both uncalled for and unnecessary.—ED. L.

NORTH-LONDON HOSPITAL.

LITHOTOMY.—MR. LISTON performed this operation on the 28th of October, on a youth aged twelve, who had suffered under the disease for some time. The operation was performed in the usual manner, but the surgeon found it necessary to divide the right side of the prostate, in consequence of the inordinate size of the stone; he remarked that he preferred taking such a step to lacerating the parts. The stone was of about the size of a pullet's egg. The operator observed that it was not often that stones of such a size were removed from subjects so young, but he had in some instances met with them much larger, even in patients under six years of age. In the present case the operator used a small adult forceps, remarking, after the operation, that it was always necessary to proportion the forceps to the size of the stone to be removed. The operation was completed within two minutes. The child has since been doing well.

BOOKS RECEIVED.

Elements of Bedside Medicine and General Pathology, or General Disease-Discourse, with a Sketch of the Origin, Progress, and Prospects of Clinical Medicine and Surgery, &c., with a Confession of mixed Medical Faith, &c. By J. S. Thorburn, M. D. London: Longman and Highley, 1836, 8vo, pp. 437.

An Experimental Guide to Chemistry. By Edward Davy, M. R. C. S., 1836, 12mo. pp. 98.

St. Thomas's Hospital Reports. By John F. South, Assistant-surgeon. No. I. Nov. 1835.

An Inquiry, physiological and pathological, into the Proximate Cause of Cholera. By Protheroe Smith, M.R.C.S., and Senior Surgeon to the Farringdon Dispensary. London. Bailliere. 1835.

CORRESPONDENTS.

A Non-professional Reader will find just such a clear and simple account of the stomach as he wishes to see, in the Third Number of a little Monthly Magazine published in London, called "The Christian Physician and Anthropological Magazine."

Our arrangements do not allow us to devote the space which would be requisite for the insertion entire of the communication of *Bristolensis*. If the writer has no objection to allow such a careful and discriminate curtailment of his paper as will separate the vein of thought and argument from the superfluities of expression which surround it, we will find room for his views.

ERRATUM.—The initial F. in the name of Mr. Daniels, attached to the letter at page 271, should have been N.

CLINICAL LECTURE

ON CASES OF

ERYSIPELAS OF THE HEAD,

Delivered in the Session 1835-36,

BY DR. ELLIOTSON.

I HAVE four cases now to mention to you, gentlemen, which were all instances of the same disease, and all illustrative of the great advantage of a particular mode of treatment. They were instances of erysipelas of the head, which is a most dangerous disease, and I would at any time rather not have to treat a patient with it; for although one may follow plain indications in the treatment, disappointment frequently attends our efforts, and patients die with signs of inflammation of the brain or its membranes, more or less effusion of fluid being found after death in or upon the brain. Many of these cases yield to bleeding, cold applications, purging, mercury, and starving. Other cases require these measures in a mild degree. In other cases, again, evacuants cannot be borne, and quinine and good nourishment are very soon required. But however plain the indications, we are so often disappointed in the treatment, that I was very thankful when Mr. HIGGINBOTTOM made known a mode of treatment which was much more beneficial than the remedies already in use. Now, it is a rare thing for one man to have four cases of erysipelas of the head all occur nearly together, and all do well. The disease is far more dangerous in those who have passed the middle period of life, and in those who have suffered from intemperate habits, or from the unwholesomeness of climate. Of these patients in question two were young men, and two were middle-aged men.

The first case occurred in a man, aged 30, in the month of September, who

said his age was forty-six, though he looked at least ten years older, and had the appearance of a dissipated man. He was a poor shoemaker. He denied that he had ever been a drinker, and also most positively that he had ever had venereal disease, but his wife is now in the hospital on account of secondary symptoms, and he appeared a most unfavourable subject for the disease. On the 15th he had been attacked with rigors, followed by pain in the head and back, general heat and thirst, and some degree of purging. On the 16th and 17th he found that his face had begun to swell; it had also a feeling of tenseness and smarting, which continued to increase. At the time of his admission, the skin of his nose and cheeks was inflamed, the redness was dingy, and there was oedema of the lower eyelids. The skin felt hard and brawny, and there was considerable pain in the head and cheek; his tongue was white, he had great thirst, and a feeling of nausea. His bowels were open three or four times a day, the evacuations consisting, he said, of clear water. Pulse 120, skin hot, hands tremulous, and he had altogether an agitated appearance. He said he had been nine years in the West Indies and America. All the inflamed part of his head was directed to be well moistened with a saturated solution of the nitrate of silver, but no medicine was given him. On the next day, the 19th, he was found to be much better; the solution had occasioned the cuticle to come off in many parts.

He suffered a good deal of smarting for some hours after the application, but was now perfectly free from pain of any kind. The pulse came down to 90, his hands were less tremulous, he had had one evacuation; his thirst was much less, though his tongue was still white, and he had not slept in the night on account of the soreness of those parts of the skin where the cuticle had been raised. On the 20th there was a little pain and swelling on the left part of the head, higher than the part to which the nitrate of silver had been applied. This he attributed to costiveness, and he was ordered five grains of calomel and ten of colocynth directly. On the 21st, as the forehead continued inflamed, the head was

had been more or less delirious, was like a person in delirium cum tremore, and had not complained of his arms. Upon further examination both his legs were likewise in the same condition. His debility had been extreme, and to have made incisions, I felt satisfied would have caused his immediate death. He could not have supported the hemorrhage which incisions such as would have been necessary to benefit him would have occasioned. I therefore contented myself with applying the caustic, but, unfortunately, on account of the violence of the man, it could not be applied properly. It was applied, as I have mentioned in a former clinical lecture, with a stick, but, through the man's turbulence, it was done so inefficiently, that there was no chance of its producing good, and it was certainly not applied until far too late to be of service, even had it been applied in the best manner. To have made incisions into the limb, even at a later period, to let out the matter, would also, I am satisfied, have been useless, because the incisions must have been carried to a very considerable extent, for on examining after death, suppuration was found down as low as the various bones of the extremities to a very great extent. It was a case in which no treatment whatever could have been adopted until it was too late, on account of the existence of the disease not being known earlier. Afterwards, when there was a probability that matter existed, I myself should not have thought of having incisions made into it. I may mention that deep suppurations existed where no caustic had been applied, just as where it had; and in many places where no inflammation could have been suspected. The inflammation had in all begun at the deepest situations, and extended upwards to the surface; for in all, the deepest situations exhibited the marks of the most advanced inflammation.

NORTH-LONDON HOSPITAL.

CLINICAL LECTURE

ON

ERYTHEMA AND ERYSIPELAS,

Delivered in November, 1836,

BY MR. LISTON.

THE last time I had the pleasure of seeing you here, gentlemen, I proposed saying something with regard to stricture of the urethra and other diseases of the urinary organs, but two very interesting cases, more than two indeed, of erysipelas, of a very

severe nature, have lately been admitted, and I think it is a pity to lose the opportunity of making some remarks upon the cases whilst they are fresh in your recollection; therefore, with your permission, I shall for the present delay my observations on urinary diseases, and take up the subject of erysipelas.

The cases to which I have alluded have been as severe as any I have witnessed for a long period. I had at one time very ample opportunities of observing this disease in an hospital that was extremely unhealthy, until the management fell into new hands, when, having the opportunity of becoming in some measure the instrument of reform, I endeavoured to amend the unhealthy condition of the institution, and succeeded in my object. Now this is a disease which is well worthy of your attention and study, seeing that it is apt to follow all sorts of injuries, slight or severe; and is a frequent attendant as well on the most trifling operations as on those of a more severe nature,—a disease which, when it prevails, is calculated to mar the best efforts of the surgeon in conducting the treatment of injuries, or in endeavouring to relieve patients by operation.

There are several forms of the disease. We meet with it both after injuries, and, to use a doctor's phrase, as an "idiopathic affection;" that is, it comes on of itself, and does not arise from or depend on any other disease. It presents different degrees of severity. It attacks merely the surface of the body, the vessels which ramify on the surface of the chorion, which you see exposed after the application of a blister, the vessels which supply the corpus mucosum, — those are principally affected in one form of the disease. In another form the whole thickness of the cutaneous tissue is diseased; and, occasionally, something more, — the parts underneath.

The one form of the disease, also, is apt to pass into the other. The erythema, so called from its red appearance, is apt to pass into the substance, and become what is called "erysipelas," a disease which involves the neighbouring tissues. We have then an intense redness of the surface, and a swelling of the parts attacked, which passes into the subjacent tissue. Thus the disease is apt to spread both superficially and in depth.

The constitution is predisposed to attacks of erythema or erysipelas. Disorder of the digestive organs predisposes to it. It is very apt to attack hard livers, and those who indulge in spirituous liquors. In such patients it will follow a trifling wound, especially any of the fibrous tissues, or of the skin, at the point of the elbow of the knee. Attacks of erysipelas are also frequently accompanied by more or less disorder of the digestive organs.

AND ERYSIPELAS.

The state of the atmosphere predisposes very much to the disease. In warm damp weather it is more frequent than in very cold or very hot weather. In spring and autumn it mostly prevails; and at those periods you can almost predict with certainty the prevalence of erysipelas from the state of the atmosphere. It also often arises from putrid exhalations, and the exposure of patients to miasmata. A very remarkable instance of this occurred some time ago, in the cavalry barracks in the neighbourhood of Edinburgh. Any one who has been in the North, on going into Edinburgh by the London road, must have observed a large piece of flat ground, covered with luxuriant and rank vegetation, and presenting an intolerable nuisance to the nose. The water from all the sewers of that beautiful town are collected into a sort of filthy, putrid rivulet, which I think they call the "Tumble," and in that way is collected in reservoirs; here and there are floodgates, and at certain periods this horrid collection is allowed to flow over and irrigate the meadows which I have mentioned; and such is the effect of this process that you cannot pass in that direction, especially just before the setting in of wet weather, or a storm, without being almost suffocated, and finding it necessary to hold your nose all the way over half a mile or more of road. I am, in fact, astonished that the nuisance is not abated. An attempt was once made to have this lovely stream covered over, and the contents carried down to the Forth; and if I mistake not, a bill was carried into Parliament with that view, but great efforts were made by the proprietors of the land to prevent the passing of the measure, and they succeeded in getting the bill thrown out. No wonder they should be anxious to preserve a nuisance which produced them, I believe, some 20*l*. or 30*l*. an acre annually, for land which previously was not worth twenty shillings. The cavalry barracks stand pretty nearly in the middle of this swamp, and some time after a regiment of Dragoons was stationed there, and on the very day following that upon which those sluices were opened, and the irrigation commenced, eight cases of erysipelas appeared amongst the troops, who were previously perfectly healthy; and before that regiment left the barracks, a considerable number of men, and two or three of the officers, were destroyed by the disease.

The disease may also be produced from exhalations from dung-heaps, or filth collected about hospitals; and I recollect that in the hospital at Edinburgh, in spite of all the precautions I could make, a quantity of matter was collected into one vessel, and every patient that was received above, was attacked with the disease, more or less extent.

The disease is propagated by

contagion. There is not the least doubt of that. One of the cases at present in the hospital shows that fact tolerably well, though a stickler might say that the woman was exposed to the same exhalations, or to the same atmosphere as her mistress, whom she attended with the disease before she came in here. I allude to the patient who is lying at the farther end of the ward No. 2. Her mistress had erysipelas following puerperal fever, and our patient was attacked with erysipelas in a few days afterwards, exceedingly severely. She was brought here, and with difficulty she was made convalescent.

I had very good opportunities of being assured that this disease was contagious, in the hospital to which I have alluded. When I became a dresser and a house-surgeon there, and for a long time afterwards, erysipelas raged in the establishment as a perfect plague. No patient was admitted with a breach of surface, an ulcer, or a wound of any kind, without suffering erythema or erysipelas; and scarcely a single operation was performed, seldom even blood-letting, without the same result to a greater or less degree. This arose from the foolish practice of washing every sore indiscriminately, as was the fashion of that day, with a sponge and water, and I believe the same sponge and water were often used for many sores, and the consequence was that a patient with a putrid sore, or labouring under an attack of erysipelas, soon became the means of spreading erysipelas through the ward; and it was only when I took charge of that hospital, and exercised a great deal of care, in introducing such a better system of dressing as is now pursued here,—after destroying all the sponges, and directing that if the wounds were washed at all, and there is no use in washing anything but the surrounding skin, they should be washed with clean water and tow,—that we succeeded in improving the state of the hospital. I was looking the other day over the list of patients on whom I operated in that hospital for stone, and I may enable you to judge of the benefit gained to the patients by these changes, when I state that of about forty cases I think not more than five were lost. The same remark applies to the operations of other descriptions; and certainly a very great number of the operations which I performed in cases where the union of parts by the first intention was necessary for the cure, such as operations for hare-lip, and the restoration of lost features, were treated with equal success. I believe that a great deal depended also upon an improved ventilation of the wards; and Sir GEORGE BALLINGALL, and many other friends, could bear me out in saying, that to such a fearful extent did the disease prevail at one time in that institution, and so difficult was its prevention, that they talked of taking off the

roof, or removing the ceiling, and renewing the floor, to see if that would do any good. Erysipelas, however, as you see, may arise from much slighter and simpler causes than proposals to unroof and refloor a set of wards would lead us to suspect.

Erysipelas is confined to the surface, and presents a bright redness, which is lost, at its circumference, in the neighbouring parts, and disappears on pressure, for a time; and the part may pit slightly when the disease is advanced, and some slight effusion has occurred in the cellular tissue. The patient complains of a burning sensation of the part, but not of throbbing or violent pain. In erysipelas the whole thickness of the skin is affected, the vessels part with more of their contents, and an effusion of serum very often takes place under the cuticle. You see it marked in this drawing. I expected to be enabled to illustrate these observations by some drawings of the disease, which, I presume, are to be found in the extensive collection on the other side of the way, and for which I wrote, but they are not forthcoming. What you now see are more like caricatures than realities, but, in the absence of better drawings, they may serve to illustrate the disease. Here are vesicles produced by the oozing of the vessels, and in consequence of which vesicles appearing, the disease is placed in the order called "bullæ," and claimed by the physician. Here is a drawing of a case of bullæ, which was admitted into the hospital; the vesications, had all formed without the existence of any previous inflammatory action. But the vesications do not uniformly occur in erysipelas, and I do not see why physicians should have the exclusive charge of this species of the disease. There is also effusion into the subcutaneous cellular tissue, always producing more or less swelling, particularly in those parts where that tissue is exceedingly loose, and easily broken up, as in the scrotum, the prepuce, and the eyelids. The effusion takes place in those parts very early in the disease. Sloughing is very soon developed in them. The effusion consists in general of an albuminous serosity — of lymph, — gelatinous-looking, but coagulating naturally, the former kind coagulating only by heat, or the addition of acids or of alcohol. In the more advanced stages, the lymphatic effusion very often becomes purulent, and you have deposits of pus in the part most inflamed and most tense; and on cutting into it either during life or after death, you perhaps find dead portions of cellular tissue with the pus. A little beyond this, lymph is found filling up the cells of the subcutaneous tissue; and yet here and there a globule of pus appears. Further off there is merely albuminous serosity; but in many cases there is a secretion of an exceedingly acrid nature, dark and putrid, which passes into the cellular

tissue and very rapidly destroys it, ultimately destroying the skin too; because, as old FARRA, a surgeon at one time in *St. Bartholomew's Hospital*, says, a man's waistcoat cannot be long on fire without his coat burning also. There is a loss of the vessels which supply the skin, which then necessarily suffers also.

This putrid secretion occurs after injury, and is similar to the fluid which is secreted from a bad ulcer. Exceedingly bad effects result from inoculation with a fluid of this kind. Nurses who wash bandages or poultice-cloths, sometimes get their fingers pricked with a pin incautiously left in the bandages, and are thus inoculated, although the matter is so exceedingly diluted, when a great degree of action is produced in the skin, and a quantity of this purulent fluid is formed in the cellular tissue. It is this sort of secretion which is found in bruised wounds. There is excitement of the surface, without time for the cellular tissue to be glued up by inflammatory action and the deposit of lymph. This acrid fluid is poured out, is extensively infiltrated, destroys the tissue, and is often the cause of the rapid spread of gangrene. Before a part becomes gangrenous, a streak, a darkness, a sort of brownish tinge, is seen on the integuments, or above the part which altogether has perished. There is a brown streak seen running in the course of the vessels. This is not a "diffused inflammation," as it has been called, of the cellular tissue, but an infiltration into it of putrid matter, which the cells of the tissue, being broken up, readily admit. The streak running in the course of the vessels is not the result of inflammation in the vessels themselves, but is the effect of the cellular tissue being there very loose, and readily admitting the serosity. The late Dr DUNCAN, junior, of Edinburgh, — called "junior," when neither very young nor very well-conditioned, — a very learned man, and long editor of the *Edinburgh Journal*, wrote a book on what he called "Diffuse Cellular Inflammation," making a sad mess of the subject, as doctors generally do when, stepping out of their proper sphere, they attempt to teach surgery, or to meddle in any way with diseases which are curable, under proper management, by the timely and judicious employment of local means. I do not mean to deny that the cellular tissue is occasionally pervaded by inflammatory action but it often suffers from infiltration following upon affection of the neighbouring investing structures. I am not very sure that in traumatic gangrene it would be a bad plan to attempt to limit the disease by a tight ligature, when, from the violence of the inflammatory fever, or from any other cause, amputation of the limb at an early time considered inexpedient, and probably, on the first opportunity, in the practice, I do so.

apply a tourniquet in such cases, though it is almost the only purpose for which I can fancy a tourniquet to be of use now-a-days.

We had a very good instance of the destruction of the cellular tissue lately, here, in a patient who was admitted with a bureal enlargement over one of the ligaments of the patella, which he attributed to kneeling hard ground at prayers, he being a very rigid Catholic; but before he was dismissed he was seized with an erythema of the scrotum. What that arose from I know not, unless it was from the accumulation of lymph. It might be from wearing dirty breeches, to which the old writers sometimes attributed the spread of venereal disease. Certainly the erythema was just as likely to have arisen from wearing dirty breeches as was the enlargement of the neck from kneeling at prayers. This erythema, however, was followed very rapidly by swelling of the scrotum, and in twenty-four hours afterwards there was a large dark speck at the lower part of it, in the cellular tissue, and the skin was only prevented from sloughing by a very free incision into the part on each side of the raphe.

Very often, after inflammation at the surface, we see more or less effusion into the cellular tissue, as well after erythema as after erysipelas, and the result of this infiltration is—long after the erythema has disappeared—the rapid formation of abscesses. In one of the first patients to whom I alluded in the female wards, a number of these abscesses formed in the scalp, several days after the disappearance of the redness of the surface, and we were under the necessity of making about six incisions into the scalp, for the purpose of evacuating the matter.

Case 1.—Having made these general remarks, I turn to the cases before us. Here is a map of the first patient, who, it appears from her statement, had attended her mistress during three days and nights, while the latter was suffering under an attack of erysipelas and puerperal fever, of which she died. On the third evening of her attendance, the servant was attacked with idiopathic erysipelas, violently affecting, inflaming, and distending, the entire surface of the head and face, and extending some distance down her back. The eyelids were so much distended that vision was completely obstructed. In this state she was admitted, being then also violently delirious. On pressing the stomach great induration and extreme tenderness were perceived. The muscles were very rigid, the pulse was 120. She was ordered some antimonial medicine, and was bled sufficient to open the bowels. The next day, which several vesicles also had appeared on the parts, were very freely discharging, and the tenderness of the scalp was confined to the hypo-

gastric region. The pulse came down to 110, and she rather improved. The punctures were repeated very freely, six or eight dozen being made over the eyelids. There was great infiltration over the eyes, so I took the liberty of putting the lancet in at the root of the nose, and ran it upwards, in the mesial line, for an inch or so, in order to allow the serosity there collected to escape in that way, and a line of the nitrate of silver was drawn across the upper part of the thorax, with a view to prevent the extension of the inflammation in that direction. She became a good deal better, and on the 28th of October, having been admitted on the 22nd, the pulse had come down to 90, and was very weak. On the 30th the pulse was 96, and very weak, and she was ordered a little port-wine, with a mixture of cyanuret of potass, tincture of hyoscinum, and infusion of rhubarb. She was not in a state to bear any further abstraction of blood, and this medicine was given to allay the general irritability, and to put the stomach into a better state, and clear the tongue. She is now convalescent, but still remains in the house.

Case 2.—On the other patient an operation was performed, out of complaisance, as the French call it. She came here to have a tumour, situated betwixt her eyelids, removed, on account of the deformity it occasioned. Her friends had advised her to have it removed, and it was dissected out, according to her desire. After the operation she preferred going to her master's house, and on the Sunday following, two days afterwards, there being on that day no certainty of my coming here, she presented herself at my house, to have the stitches taken out, the wound having been brought together by two sutures. On her way home from my house, or on her road to chapel, I do not know which, she was traced into three or four gin-shops, which she did not leave, it is to be presumed, without indulging in a little drop of comfort, and the consequence was, that on the next Tuesday she was attacked with erysipelas of the head and face, and on Wednesday was admitted here with inflammation of a rather severe character. Her pulse was very strong and full, as it had been from the commencement, such as you might expect in inflammatory fever, and I felt warranted in abstracting a little blood. I therefore ordered about ten ounces to be taken away, and this on the next day was found very much buffed and cupped. Common aperient medicine not affecting her, it became necessary to give her croton oil more than once. The parts were punctured, and afterwards fomented. Although at first she showed signs of inflammatory fever, she very soon became weak and low. The type of the fever changed entirely. The tongue became loaded with a brown crust; the pulse was weak, indistinct, and exceedingly

quick. In a day or two she became delirious, like the other patient; it was even necessary indeed to put her into a strait-waistcoat. This delirium was followed by coma. One day the redness had gone off suddenly, which I am inclined to attribute to her having been exposed to a current of cold air by the opening of the water-closet door, next to which her bed was placed, and she was in a most precarious state, and had, in fact, every sign of dissolution except one. She was lying stretched out in bed, her extremities were cold, with scarcely any pulse,—none at the ankles; she had laborious breathing, the mucous rattle, and a lifting up of the nostrils; in short she was comatose—quite insensible—and could not be roused in any way. The only symptom which encouraged me to hope that she might still struggle through was, that she had not lost the power of swallowing. She took any thing that was offered to her,—first port-wine, and afterwards some gin—with very great readiness, and in that way she has been supported until now, and though she is still in a very precarious state, yet I think there is some slight chance of her recovery. I may add that, in addition, a large blister was applied to the back of the head and neck, with a view of producing a diversion of the secretion from the base of the brain. We find in many cases, as in this one, that when the erysipelas goes away rather quickly, effusion takes place at the base of the brain, and sometimes symptoms arise which would induce us to suppose that effusion had taken place, but without our afterwards being able to discover any effusion of serum. Professor BEANS has stated, in his "Principles of Surgery," that in erysipelas "the high excitement of the sentient extremities of the nerves, from inflammation, often causes torpor of their origin, and produces all the symptoms of hydrocephalus, without a drop of water, or any trace of inflammation, being discoverable." The probability was—from the symptoms in this case—from the deep coma observed—that effusion had commenced, and a very large blister was, therefore, as I have said, applied over the back of the head and down betwixt the shoulders, and this was followed by good effects. The patient was next day better, her breathing became easier, the lifting of her nostrils went off, the extremities became more warm, and she now makes attempts to speak, and seems to know what is going on around. All this shows you that in such a case it is unwarrantable to stand by, and to give up the patient as lost without making any remedial attempts. In the most desperate case of this disease, or of any other, it is your duty to act upon the maxim, that so long as there is life there is hope. As long as the patient can swallow, you must endeavour to keep up the circulation and prevent sinking. There could be no

better instance of the happy results of persevering to the last, than this case has furnished, and I have seen many other far-gone cases in which all the powers seemed to have gone except that of swallowing. I recollect a patient who was under my care, about whom I was much concerned, who had submitted to the severe operation of removal of the upper jaw for tumour involving it. Erysipelas of the head and face supervened, but, from some cause or other, the erysipelas suddenly disappeared, and coma came on, and a practice was pursued in that case very similar to what was adopted in this one, and the patient ultimately recovered.

Treatment.—As regards the treatment of erysipelas, I caution you that although there is an appearance of strength and inflammatory action, there is no great power to sustain that action; and if you remove blood in any great quantity, the patient will be liable to sink rapidly. The type is very often, almost from the first, of the typhoid nature—a low fever. Though it commences as an inflammatory fever, it is very apt to change into the typhoid. On looking over Mr. WAXBORO'S excellent book "On Blood-letting" the other day, I observed that he mentions, amongst many other cases in which he recommends blood-letting, that of a lady labouring under erysipelas, to whom he was called, when, on entering the room, he found a quantity of wine-and-water by the bed side, which she had been ordered to take, with bark, every hour. In that case he says he changed the practice, and bled her three times. But that is a practice which I would not have you follow in all cases, though the lady recovered. You must be cautious in these cases, of resorting to blood-letting. You can take away blood by puncture, a practice first introduced by Sir RICHARD DUNSON, with great relief to the vessels affected, allowing their serous contents to escape, and getting rid of the swelling,—preventing, indeed, the formation of matter, or, what is worse, the destruction of the cellular tissue by sloughing.

In other cases, again, there is a great deal of effusion into the cellular tissue, between the coverings of the cranium, or in an extremity, and you will be able abundantly to empty the vessels, to evacuate the effusion, and to accomplish your purpose, by having recourse to one or two incisions of no great extent. That practice, however, you could not follow in the face, with any propriety, from fear of producing deformity; but still you might employ there a great many punctures, which are preferable to leeches, because the bites of leeches very often become irritable, and rather tend to keep up the inflammatory action. In erysipelas very often follows the application of leeches. By those punctures remove as much blood as you can, and the patient certainly

such. In the scap you are very often obliged on to make incisions to evacuate the matter. Without these, in fact, matter will form in very great quantity, in a large bag, sometimes even sloughing of the fibrous tissue occurs, and, ultimately, the destruction of the patient. I have again and again seen sloughing of the aponeurosis of the scapular bone, where the patients have struggled through, in spite of the treatment, and in spite of the neglect, though a great many of such patients have died. You would therefore make the incisions, and at an early period, that is, as soon as the presence of matter is indicated. You are not to wait for the redness of the integument, or for the thinning and pointing of the abscess, but must make the incisions into those parts which feel boggy. It is much better, indeed, that you should be disappointed occasionally in not finding matter, than that matter should be left under the scalp. In erysipelas of the extremities, where the formation of matter, or sloughing, is threatened, you must use pretty free incisions. The suggestion of this practice is maintained by modern writers on surgery, but the fact is that the old surgeons knew something about it, as well as the surgeons of the present day. Here, for instance, is an old writer who says, that "scarifying the skin in gangrene is a very idle practice, unless the surgeon hath sagacity enough, when the membrane is not destroyed, but only ready to suffer, to cut largely through it, and thereby let out the inflamed juices, and by that means take off the distention." If that is not to the point, I am very much mistaken. The writer proceeds to say, "In such an act, the surgeon shows both judgment and resolution, and such good treatment continued may cure the patient." There is just as much in this short quotation, as you will find in some of the modern sayings.

Now it is not necessary to make an incision from one end of the limb to the other, having searched out the point where the infiltration is greatest,—where you think there is a certainty that the cellular tissue is broken up, and where the matter, if any, may be discharged, you should there make the incision; and one incision is just as good as half a dozen, or a very long or large one. The patient Brown from whom this sketch was made, was admitted into the hospital one time ago. He had received a blow on the point of the elbow. I do not know whether there was any wound: but if any existed, it was small; but I again warn you, that those wounds over the point of the elbow,—wounds of the fibrous tissue,—over any joint, are very apt to be complicated by erysipelas. This bruise was followed by violent inflammation, and the appearance which is seen here, as you may have seen, there was a

white appearance on the surface, which I attributed to the application of some cooling lotion or other, very likely containing Goulard's extract, and there was a great degree of tension and throbbing. Into the part which was principally infiltrated I made an incision, and a quantity of blood was evacuated, and sero-purulent matter—ill-digested pus. Immediately upon the incision being made, the redness went off. In two days he returned here with a discharge from the wound, in no great abundance, perfectly healthy, and with the whole of the inflammation gone. The man was cured, in fact, upon the spot.

Now as a local application, I would recommend to you, in preference to any other, frequent fomentation, and with fluid of a comfortable temperature. You may have your liquid for fomentation, medicated or not, as you choose. Patients, however, are inclined to use, and persevere with, medicated applications much more readily than others. You may have simply a couple of bags, containing chamomile flowers, in a basinful of hot water; one of those bags, after lying awhile, is to be squeezed dry and placed on the part, and the two are alternately to be applied, hot and hot, for half or three quarters of an hour at a time. These applications are very grateful to the feelings of the patient, and give much greater relief than any other. They act beneficially by keeping the surface perspirable, promoting the discharge from the surface, and increasing, also, to a certain extent, the secretion into the cellular tissue,—a means which nature employs to relieve the excited capillaries. When effusion can take place readily into the cellular tissue, the inflammation is of a milder kind, the patient suffers much less, and great advantage may be derived from increasing this effusion instead of preventing it. After the fomentations you may dust the diseased part over with some bland powder,—flour, or any thing of that kind,—with a further view of relieving the feelings of the patient and of protecting the tender and irritable surface. This prevents any sudden change of temperature, or blast of cold air, from repelling the inflammation; but you are still to foment, after the incisions or punctures have been made, from time to time, say three or four or five times a-day, according to circumstances.

I should have mentioned, in speaking of the constitutional treatment, that it was essentially necessary to put the digestive organs into proper order. The bowels must be emptied, and any uneasiness which exists about the stomach and liver must be relieved by the application of leeches, and you will find a great advantage after the bowels are emptied, from the exhibition of small doses of antimonial medicines, combined, if you like, with a little calomel. The works of DESAULT, which were re-

MR. LINTON ON Erysipelas.

vised and edited by BACWAT, contains an excellent memoir on this subject, where the practice of exhibiting small doses of antimony is recommended strongly, and this practice you will have no reason to regret. The antimony keeps down the force of the circulation, it acts beneficially on the bowels, and it promotes the secretions generally, while undue inflammatory action exists. Afterwards it will be necessary to support the patient's strength by every possible means, by nourishing food, and in some cases even by wine and stimulants of one sort or another.

Now as a means of preventing the spread of inflammatory action, the nitrate of silver may be used, drawing with it a line beyond the skin which is affected, a considerable way from it. This practice has been pursued in both of those cases that are now in the ward, and very great advantage indeed may be derived from adopting it. The inflammation very rarely oversteps this line. How that happens I shall leave to some of you ingenious gentlemen to explain, but an action is evidently established in this way on the surface which is incompatible with the progress of the erythematous blush. The nitrate of silver is a very good application where there is but a slight degree of erythema, and when it does not involve a large surface. Sometimes trifling erythema follows a puncture with a pin, or a fish-bone, or something of that kind, impregnated with putrid matter; and when the inflammation is limited to a finger, or the back of the hand, the nitrate of silver may be rubbed on with perfect propriety. The inflammation in this way will be extinguished; but if a large surface is affected, the nitrate of silver, in driving inflammation from the surface, is apt to cause it to affect some other part, and an infiltration is very likely to supervene, so that, instead of the mere surface, the whole thickness of the chorion will be inflamed, and a considerable degree of swelling, and perhaps a destruction of the cellular tissue, will follow. My attention was directed to this a good many years ago, in treating a case of erythema of the hand. It was pretty extensive; it passed over one or two fingers, and involved the back of the hand to above the wrist. I rubbed the nitrate of silver over it, thinking I was doing no harm, but the next day I was under the necessity of allowing a quantity of putrid fluid to escape, by incision along the whole of the back of the hand, and I do not think the patient escaped without a considerable destruction of the cellular tissue of the part. This is of little consequence compared with the production of inflammation of the internal organs, which happens when the inflammation disappears suddenly, of itself, or when it is repelled by cold lotions. The patient then becomes comatose, or his breathing is embarrassed.

It is found, indeed, to be much more easy to drive the inflammation to internal organs than to bring it back again. I have seen blisters and cauteries applied with the latter view, without effect. I have seen, both in public and in private, cases of erysipelas treated by the nitrate of silver, where the whole surface has been rubbed over and blackened with the caustic. In others, lines have been drawn here and there, transverse, longitudinally, and "glattendicularly," as our transatlantic brethren express it. Some of the patients have done well; in others extensive destruction of the cellular tissue, with formation of diffused abscess, has occurred. This is very likely to be the case, and through the hardened and blackened epidermis it is not easy to discover the mischief early enough to adopt the proper means for giving relief. I am not quite up to the *rationale* of the practice, or the precise intention of those who recommend and pursue it. I had once the pleasure of being a colleague with a gentleman who took the very odd notion into his head that he could cure all patients who were labouring under the disease in question by painting them over *blue*,—perfectly blue,—with mercurial ointment. I should think that long before this he has seen the error of his way.

I may add, that sometimes the mischief of erysipelas is not confined to the cellular tissue and skin only. Now and then even the bones are affected by it. Muscles are affected by it occasionally, and I have seen great portions of them slough out. I have seen a limb rendered perfectly useless in consequence of the destruction of the fascia and the muscles. Sometimes you find the hands contracted, and put into a very awkward position. Here is a specimen, in which the disease commenced with erysipelas, producing this effect on the bones, in the foot. The patient was treated by a physician, and a very rising one, now deceased, in a fever hospital; and whilst everything was done, I have no doubt, to moderate the constitutional disturbance, the local symptoms were allowed to go on. I saw the patient when he was moribund. The whole limb was swollen, and he was then hectic; he was, in fact, in the last stage of existence. A few days afterwards he died, and I preserved the bones. See their condition. The local mischief had been going on for many weeks; the periosteum had been destroyed; the bone was penetrated by ulceration; even the knee-joint was involved; there was actually necrosis of several parts of the articular extremity of the tibia. Here is another specimen, where the disease of the bone was not quite so extensive, where the disease commenced in the skin. It was a violent case. In fact, however, I would call it,

MR. TYRRELL ON WOUNDS OF ARTERIES.

"phlegmonous," "gangrenous," and "necrotic;" but the termination in one or other of these ways, must depend very much upon the skill and activity of the surgeon. It will neither be "phlegmonous," nor "gangrenous," nor "necrotic" (to coin a new adjective), if the surgeon knows what he is about, and gets the patient under his care early enough in the disease. There should be no destruction of the cellular tissue, far less of the skin or of the bone in those cases.

I do not think, gentlemen, I have anything else to say on this subject on the present occasion.

ST. THOMAS'S HOSPITAL.

CASES AND CLINICAL REMARKS.*

NEW TREATMENT OF WOUNDED ARTERIES.

CASE 1.—*Wound of the Brachial Artery in Venesection.*—Eleanor Hughes, ætat. 25, married, admitted under the care of Mr. TYRRELL, March 3, 1834, occasionally suffering from headaches, and in being bled this morning the brachial artery was wounded. Compression was made above the puncture, but she lost eight or ten ounces of blood, and became extremely hysterical. Soon after, a "ring tourniquet" was put on, so as to compress the artery near the insertion of the coraco-brachialis. The ring tourniquet consists of a metal ring, larger round than the limb, and about an inch broad at the circumference, which is tapped so as to admit a screw, to the lower end of which a pad is fixed, the outer end having a small handle to turn the screw, so that the pad can be carried to or from the centre of the circle. This instrument makes pressure only on two parts—by the pad on the artery, and by the portion of ring on the limb immediately opposed to the position of the artery; thus it does not interfere with the lateral circulation. A firm compress, wetted with cold water, was applied over the wound; the limb was bandaged *tightly*, from the fingers to the tourniquet, and the arm was elevated so as to favour the return of the blood to the heart. The whole limb was enveloped in flannel.

9 p.m. A dose of ammonia with camphor mixture relieved the hysterical symptoms. Tolerably easy, but rather restless; pulse soft and compressible, tongue slightly furred.

See Appt Sed. III xxx.

Passed a tolerable night, complains of

very little pain in the arm, which is of the same temperature as the rest of the body.

6. Bowels have been opened once only, and that by medicine, since her admission. *Complains of pain in the arm, and is very restless; pulse 90, and soft.*

7. The ring tourniquet slipping very much, a common tourniquet was put on instead. Whilst removing the compress and bandage from the puncture, about a teaspoonful of healthy pus escaped, which afforded her great relief. Simple dressing and a soft compress of lint were applied, and the whole was secured by a slight bandage. A common arm-splint was placed on the under surface of the limb to keep the arm extended. Pulse 94. Ordered *Colecyth* and *Calomet*, and an enema every evening if necessary.

8. Has been rather sick; the arm has been very easy; very little discharge from the wound, and no hemorrhage, although the tourniquet has been slackened considerably. Bowels relieved three times; pulse 90, and soft.

9. No sickness, but says her arm feels hot and burning. On removing the dressing, a little pus escaped, but the wound is granulating.

10. Her arm is very easy. As, however, she complained of great pain from the tourniquet, it was taken off. No hemorrhage has occurred since.

15. The wound nearly healed; there is much adhesive deposit still left around the artery, through which it may be felt pulsating slightly; general health tolerable.

17. Going on extremely well; arm supported on a splint in a semiflexed position: a firm compress is still applied over the puncture.

April 10. Puncture perfectly healed; the adhesive deposit now quite absorbed; the artery can be felt pulsating in its natural situation, but not at all increased in size, strength, or volume. On the 16th she was presented cured.

Remarks.—"I have seen the patient frequently since" (said Mr. TYRRELL, in commenting on the case), "and she can use her arm without difficulty, even in heavy work. There is no appearance of disease of the artery or veins. This is the fifth case of puncture of the brachial artery in bleeding, which I have thus treated, in every instance, successfully. In one case I had an opportunity of examining the parts several weeks after the cure had been completed. The patient was at St. Thomas's Hospital, and in performing venesection, one of my dressers punctured the brachial artery; I was sent for, and adopted the treatment prescribed in the foregoing case, with success. Some weeks after, the patient died suddenly, when I found that the median vein had its canal obliterated for half an inch above and be-

*The cases and observations are usefully collected and entitled "St. Thomas's Hospital," and published by Mr. J. F.

low the puncture; it was adherent to the artery; the wound of which was firmly united, and its caliber perfect. The parts are preserved in the museum."

CASE 2.—Wound of the Radial Artery.—W. Lowe, *etat.* 22, carpenter, admitted under Mr. TYRRELL, Nov. 11, 1834. In cutting bread with a penknife, the knife slipped, ran into his wrist, and was immediately followed by a large gush of blood, which he commanded by pressure till he arrived at the hospital. On examination, a small wound in the integuments was observed, which penetrated to the radial artery as it passed over the insertion of the *mus. supin. long.* Large gushes of blood pumped out rapidly, but were restrained by pressure of the vessel above. A common phial-cork having been split vertically, one portion of it, wrapped round with lint, was placed with its convex surface upon the artery above the wound, and tightly confined with sticking-plaster, which immediately arrested the hemorrhage. The edges of the puncture were then brought together with plaster, a compress was applied over it, and the whole was confined with a roller. The hand was tightly bandaged, from the fingers to the wrist, and the limb kept elevated.

Nov. 12, 13, 14. Going on well.

17. On opening the bandages to-day, union had not taken place, but the bottom of the wound was healthy and granulating. There was not the least bleeding either from the wound, or on removing the compress on the radial artery. He had some pain and *oedema* of the hand, *owing to the bandage round the wrist*, which was therefore loosened, the arm and hand well kept up by pillows, and a large poultice was applied to the hand. In the afternoon bleeding again occurred; the compress having been taken off, it was reapplied; the limb was confined as before, and the hemorrhage stopped.

24. No disposition to bleed since; the wound only requires cicatrization for its perfect cure.

28. The compress is still retained, but not so tightly as to prevent the flow of a certain quantity of blood.

Dec. 5. No return of bleeding, the external wound is almost healed, and on the next day he was presented cured.

Remarks.—"The vessel," Mr. TYRRELL remarked, "was wounded in a position in which it could have been secured without difficulty, but the case illustrates the success of the plan. The treatment I consider especially applicable to wounds of arteries difficult to get at by operation, without risk to other important structures, as in the case of puncture of the brachial artery, in venesection, or in wounds of the palmar or plantar arteries. I have treated all the above named vessels, on the plan described, successfully. The principle of the treatment consists in arresting or diminishing

the flow of blood to the injured vessel, by pressure on the trunk or trunks communicating with it, in keeping the wounded part carefully adapted by moderate pressure in preventing venous congestion, by position and support of bandage, and in forming the adhesive union by perfect quiet. It is necessary to persevere for two or three weeks to ensure a perfect cure."

BROKEN CATHETER IN THE BLADDER EXTRACTED THROUGH THE URETHRA.

Joseph Strangmore, *etat.* 40, admitted under Mr. TYRRELL, Jan. 11, 1835. Has had stricture for some years, and passes instruments for himself. This morning, however, on passing the instrument, it met with great resistance in the bulbous part of the urethra, and on using force the catheter (a No. 6) gave way an inch above its curve, where it had been once soldered. He immediately set out from Reigate, twenty-one miles from London, and walked a considerable part of the journey. A sound introduced by Mr. TYRRELL evidenced the piece of catheter lodged at the fundus of the bladder transversely, its extremities being held with some firmness by that viscus. He dislodged it by passing the end of the sound beyond it, and drew it forwards to behind the prostate gland, where its position was still transverse. The bladder seemed to contain several ounces of urine. The sound was withdrawn, and one of Weiss's instruments for extracting small calculi, which was nearly straight and had a strong spring, was introduced. One extremity of the foreign body was now free, and after several unsuccessful attempts, was seized and cautiously brought into the urethra. With the finger in the rectum to compress the urethra between the foreign body and the bladder, so as to prevent any retrograde movement of the former, the piece of catheter was then drawn out. It measured three inches in length. The examination and operation together occupied about twenty minutes.

Jan. 14. Feels quite well, and has passed his water much more freely than for some years past.

The museum of the hospital affords several portions of catheters &c. removed from the bladder, but all by the *lateral operation*. Mr. TYRRELL says he believes "that this is the first instance in which an attempt has been made to extract by the urethra, and he trusts the publication of it will prevent the more severe and hazardous operations, in cases of a similar nature, for the future." How forcibly these latter observations might be made to apply to cases of stone in the bladder, and extraction by lithotomy, when that operation has not yet been tried, is a subject for consideration.

**ACTURE OF THE TIBIA AND FIBULA,
WITH PARALYSIS ON THE RIGHT SIDE,
FROM DEPRIVATION OF CUSTOMARY
STIMULANTS.**

Samuel Wiseman, ætat. 49, admitted under Mr. TYRRELL, Sept. 22, 1835. While rather intoxicated he had slipped down and broken both bones of the left leg, at about the middle, where they had been already fractured five times. Much confusion attended the accident, and there was considerable spasm of the surrounding muscles. The limb was placed on a pillow, spirit-wash was applied, and next day the leg was put in splints and placed in a swing-box. *R. Mist. Senn. Comp. p. c. n.*

Oct. 2. He complained of headache, which continued the next day. On the 4th, his bowels were freely relieved by medicine given the night previous; but he still complained of headache, and seemed rather heavy, and the head was hot. *R. Pulv. Jalap. c. Hydr. ʒi, hac nocte. Lot. frigid. capiti.*

5. He complains of pain in the head, and has partial paralysis of motion in the left arm; the sensation is perfect; entire paralysis of motion of the left side of the face, but the tongue is drawn towards the affected side; pulse 72, and beating pressure. *C. C. ad ʒvjoscapiti. Abrass. capiti. applic. Lot. frigid. Rept. Pulv. Jal. c. Hydr. stat.*

8. Has been frequently delirious; the paralysis continues; pulse irregular, and very compressible; bowels open. He was ordered a pint of porter, and four ounces of gin daily, which latter he began to take next morning.

10. Slept well; no delirium; pulse firmer; symptoms of paralysis subsiding.

13. The paralytic symptoms have entirely subsided, and on the 4th of Nov. the limb was removed from splints, and the fracture found firmly united.

Remarks.—"This case," said Mr. TYRRELL, "is one of extreme interest.—first, as regards the injury of the same limb several times before. It is unusual to find, at the middle period of life, many fractures occurring in the same individual. I have, however, had under my care a patient several times who is a remarkable instance of *fragilitas ossium*. He had been the subject, when I last saw him, three or four years ago, of twenty-two fractures. Scarcely a cylindrical bone of any size had escaped. In consequence of these fractures he has lost in height from seven to eight inches. The first time I had him under my care, was the consequence of fracture of one thigh-bone, and the other had been fractured previously. The consequence of different surgery, that the bones were shorter than the

one for which he came under my care. He had worn an iron to make up the difference in the length of the two limbs, and it enabled him to move himself about, but with some inconvenience. Finding this, I stated that it was possible to set the recently-broken limb to the same length as the one formerly broken, and at his wish I did so. I made an angular union of the second limb, and reduced it to the same length as the other, and he was enabled afterwards to make progression more easily and rapidly. Wiseman appears to have that condition of bone which renders it extremely brittle. In such cases, unless at an old period of life, there is almost an equal facility of union. In the man who had had twenty-one fractures, the accidents were repaired with great rapidity, the union of fracture of the femur being perfectly firm at the expiration of three or four weeks.

In examining particularly into Wiseman's case, it may appear remarkable that the man should suffer from headache, and suddenly have the paralysis displayed, without any active mischief in the head. But there has been a *portion* of the upper part of the spinal chord deprived of the due quantity of blood which is essential to its functions, and it thus influenced merely those portions of the body which I have stated.

I have had several somewhat analogous cases under my care. The first instance in which I had a distinct perception of such a case in a surgical patient, was in a coal-porter, who became intoxicated, tumbled from a waggon, and had both wheels pass over his arm, when so much were the parts disorganized, that it would have been difficult to recognise them as belonging to the human body. Amputation was resorted to. For two or three days the man went on extremely well, but on the third or fourth day the man was suffering from erysipelas. I found the parts, previously united, again open, the bone exposed, and the patient delirious. I then learned that he had been addicted to taking a large quantity of stimuli. The pulse was irregular, not intermittent, but easily compressible; sometimes the arteries appearing to dilate, and sometimes to contract more than natural. I immediately sent for a pot of porter and a gill of gin, and gave it into his hand, when he took nearly the whole at a draught, went to sleep, and awoke after many hours perfectly sane. The erysipelas subsided, healthy granulations formed on the stump, and by the continuance of a moderate quantity of stimuli, he went on without a check, and did well.

One, perhaps, of the most trifling injuries inflicted by an operation, is that for cataract. However, sometimes patients, at an advanced period of life, lose an eye from the want of power to carry them through the cure. A short time since I operated on a feeble, man between sixty and seventy years

of age, and extracted a cataract. Two days after, the apothecary came to say that the man was complaining of pain. The apothecary had employed leeches and blisters to subdue inflammatory action, but seeing that the patient's countenance was pallid, his hand cold, and the pulse irregular, I decided on giving stimulants, in spite of local pain, redness, and swelling. I ordered him a dinner of good broth, meat, and beer, and also a small quantity of spirits. On the following day but one, when I paid the usual visit with the pupils, we went up to see the man, and, rather to my surprise, the section was united, and the eye appeared as if no untoward symptom had followed the operation. The stimuli saved the eye. We have further illustrations of this point in *erysipelas*. In one instance a patient recovers rapidly under the abstraction of blood, and in another it would be injurious. Abraham's Ward, being low and close, was formerly especially the seat of such cases in this hospital. In that ward I have had four or five patients suffering from *erysipelas* at once. One of the patients has been taking five grains of quinine every three or four hours, and a pint of porter and a bottle of wine a day, and he has recovered; and the other, a bed or two off, has done well under loss of blood and powerful purgatives.

Applying these views also to medical cases, I formerly had many opportunities of conducting *post-mortem* examinations in the hospital and out of it, and of examining cases where the patients had died of fever, and in children, of measles, scarlatina, and so forth. In many of these cases we found that the patients had suffered from a serious *effusion*. Very often rallying from the primary disease, children are seized with local pain in the chest, in the liver, or head; some important viscera has, according to the doctrine generally taught, apparently become congested or inflamed. The fact I believe is, in most of these instances, that the viscera has really suffered from a *deprivation* of blood, and death is consequent on serious effusions. Thus you will find the cellular tissue of the lungs gorged with serum; the cavity of the pleura half full of fluid; and, where the symptoms affect the brain, you find its effusion in the ventricles at its base. Thinking over these cases, and conceiving them to be somewhat analogous, I was led to make the above observations. Where there is strength there is no objection to moderate counter-irritation; but where there is irregularity of circulation, the abstraction of blood is always mischievous. The great reason why such depletion is resorted to over and over again is, the slight temporary relief which it affords. In the case before us the man was cupped and leeches, and he appeared to be better for a short time, but he afterwards became more restless and disturbed, and then he was relieved altogether

by stimulants. If such patients were on good diet, and had warm clothing, and pure atmosphere, I believe very many cases would be lost that there are at present under circumstances such as I have named.

HYDROCELE TREATED WITH SETON

Case 1.—Richard Drake, *etat.* 32, admitted under Mr. GREEN, April 3, 1835. Of unhealthy aspect, rather stout, fair, and intemperate. Twelve months since he struck his scrotum against a gate, and it became tender and rather swollen; these subsided, and in three weeks he noticed a swelling at the lower part of the scrotum, unaccompanied with pain. It first increased, and then remained stationary for six months, after which it again increased. The scrotum is now about the size of a very large pear; fluctuation is very distinct, but there is only slight transparency. The testicle is situated about the middle of the hinder part of the tumour.

May 20. The operation was performed as follows:—A trocar and canula having been introduced, about eight ounces of fluid were drawn off. The canula still remaining in, a needle six inches in length and as thick as a probe, with a trocar point at one end, and an eye at the other, was introduced, aimed with twelve threads of ordinary seton-silk, into the canula, and having been carried upwards perforated the tunica vaginalis and integuments, near the upper and fore part of the swelling, and was drawn out by that aperture. The canula was then removed, and the ends of the thread were tied loosely together over a space of about two inches.

21. Eight a.m. Slept tolerably well; slight headache; tongue white and moist; rather thirsty; skin warm; pulse 90 and full. The scrotum is about half as large as before the operation, and has a slight blush upon its surface, but there is tenderness only in the situation of the testicle. No pain in the loins, as in some instances directly after the operation.

One p.m. Headache; skin hot; tongue white and dry, with thirst; pulse 90 and hard. The surface of the scrotum is red, and its size nearly equals that of the hydrocele; it is tender when touched, and he complains of a dragging pain along the spermatic cord. He has also considerable pain in the loins and down the insides of the thighs. The threads were withdrawn after twenty hours, and were followed by a drop of pus.

Three p.m. Pulse 86; all the symptoms of excitement are diminishing. The inflammation gradually subsided. The effused fluid was absorbed, and the scrotum had attained its natural size shortly prior to

June 16, when he was discharged.

HYDROCELE WITH SETON.

Case 2.—William Penning, *ætat.* 34, admitted under Mr. GREEN, July 1, 1834, a spare man, of intemperate habits. Seven weeks since he strained himself, and on the following morning observed his scrotum swollen at the lower part to twice its usual size. When now admitted, the swelling exhibited the usual appearances of hydrocele.

July 11. The operation by seton was performed as in the preceding case. The seton was withdrawn after *twenty-four* hours, the usual symptoms of inflammatory action having appeared.

Aug. 9. The cure has gone on satisfactorily, and the cavity of the tunica vaginalis having become obliterated, the scrotum has resumed its natural size. He was therefore presented cured.

Case 3.—Thomas Spencer, *ætat.* 35, omnibus driver, admitted under Mr. GREEN, Sept. 25, 1834, short and stout, but soft and flabby, and his appearance indicating intemperate habits. The disease began four months since, and four days ago the swelling became painful and inflamed; and within this time he applied a hundred leeches, but without material benefit. When admitted, the swelling was about the size of two fists; and, instead of being pyriform, as usual, it retained more the shape of the testicle. It was tender on pressure, and quite transparent.

Sept. 30. About twelve ounces of fluid were withdrawn, and the seton was introduced as in the other cases. He passed a restless night, and next day the scrotum was swollen to about a third of its former size; red and painful, and he has some pain in his loins, accompanied with slight fever. The seton was withdrawn after *twenty-four* hours.

Oct. 3. Swelling and pain somewhat diminished, but the redness still continues.

6. The swelling continues subsiding, but the scrotum is still painful on pressure. In other respects he is much improved. On the 10th he was discharged for disorderly conduct.

Remarks.—These cases are intended to illustrate a plan of treatment, of which Mr. Green says, "that although not altogether novel, it may, perhaps, be deemed an *improved* method of effecting the radical cure of a hydrocele." Mr. Green's clinical observations on the patients extended to the particulars of five other cases. Of the above cases, he says, "the first completely answered my expectations. The second and third were also completely successful, and we have only to draw attention to the fourth." On the other five cases he says, "The first case was a partial cure, the seton was withdrawn too early, in consequence of the pain experienced after a very few hours. The opera-

tion was performed at one o'clock, and the seton was withdrawn at ten. Probably the irritation tended to produce a quicker re-accumulation of the fluid afterwards, for it was performed again, and it is worth notice in this case, that the same individual evinced much less disposition to inflammation in the second operation than in the first, although the second operation quickly succeeded the first." Another was successful, excepting that there was a little suppuration in the cellular membrane. In another, suppuration took place in the cavity of the tunica vaginalis, which rendered it necessary that the tunic should be slit open, in order to allow the escape of the purulent fluid. In another the success was not complete, but in that case it appears that two previous operations by injection had entirely failed. In the last case a second operation was required. On the subject of the radical cure of hydrocele, some remarks, amongst others, to the following effect, were made by Mr. GREEN in a clinical lecture on the subject:—

"The object of the radical cure is that of causing such a *change* in the tunica vaginalis as will prevent the reaccumulation or reproduction of the fluid. It is generally stated, that the object is to *obliterate the cavity* of the tunica vaginalis, by causing adhesion of its sides, but a preparation in this hospital exhibits a tunic, taken from a person in whom the radical cure was effected by injection, and in whom no fluid was reproduced, with the cavity as perfect as it might be in the healthiest person. I can very well conceive that a slight inflammatory action may take place so as to close the exhalant arteries, at any rate in sufficient number to prevent any redundancy of the secretion. I strongly suspect, that in many instances of the radical cure of hydrocele, no more has been done than is to be seen in this preparation; and if we could always hit the quantity of inflammation which should produce this, and *no more*, it would be a better treatment than causing the obliteration of the cavity. But, unfortunately, under all the plans of treatment hitherto adopted, the quantity of inflammation cannot be regulated; unless, indeed, in the cases above cited, a method is offered which will aid us in adjusting the requisite degree of inflammatory action. Surgeons, however, conceiving that the object was the obliteration of the sac, have adopted various plans of a very severe kind, often unsuccessful, and sometimes fatal, viz. the method by *incision*, which consisted in laying open the cavity of the tunic from top to bottom; that by *excision*, in which the whole reflected portion of the tunica vaginalis was cut away; the method by *caustic*; the plan of *seton* as used by Mr. Pott, who carried a seton through the tunic, and then allowing it to come away by ulceration, thus laid open the tunic.

These were all adopted to cause suppuration and excite a granulating process by which the cavity should be filled up and obliterated.

"The treatment most generally adopted at the present day, is that by *injection*, and I suppose that most surgeons would be ready to bear testimony to thousands of hydroceles cured in that way, without the least ill consequence; but so uncertain is the degree of inflammatory action that will be excited, that under apparently the same circumstances, the inflammation will be in some cases excessive, and in others insufficient. There are likewise no circumstances by which a judgment can be formed, at the time of the injection, as to what exactly the *subsequent* effect will be respecting the quantity of inflammation. One person will complain of extreme pain from the injection, and, perhaps, rendered cautious by that symptom, you allow the fluid to escape; but notwithstanding this pain, he may not have sufficient inflammation to cure the disease. Another patient will scarcely complain of any pain, and you are perhaps induced to allow the fluid to remain within the tunica a longer time than ordinary. But instead of the inflammation being proportionate to the pain, there may prove excessive inflammation, which subsequently is both inconvenient and dangerous to the patient. But there is another objection to the plan of injection, which rather applies, however, to a possible want of skill in the operator. The stimulating liquor may be thrown into the cellular membrane of the scrotum instead of the tunica vaginalis, or escape into the cellular membrane instead of through the canula. The accident may easily take place; I recollect a case in which a patient died from it.

"After weighing all these circumstances, it struck me that if a seton were carried through the tunica vaginalis, there would be a sufficient source of irritation, and at the same time the opportunity of *regulating its degree*, that is, that the seton might be allowed to remain till there were symptoms of such a degree of inflammation as is requisite for the change necessary to be produced in the tunica, and that the seton might then be withdrawn, and no further effect be produced than is necessary either to change the surface of the membrane or obliterate the tunica. Generalizing the facts which have occurred in eight cases thus treated, I venture to say that the plan of treatment is well adapted to answer the end for which it was intended. In one case there was excessive inflammation, and a *suppurative* process in the tunica vaginalis; and the possibility or probability of this occurrence is perhaps the most serious objection to the operation. It might, indeed, raise a doubt on the principle itself of the operation. You introduce an extraneous body into the tunica, and allow it to remain till inflammation is produced, and

it is possible that the inflammatory action excited by extraneous bodies may tend to the *suppurative* instead of the *adhesive* form of inflammation. As, however, this result was only observed in *one* case, and no such disposition was manifested in a number of cases, of which the success was perfect, we are perhaps warranted in drawing a conclusion generally in favour of the effects of the seton. Of course future cases (and I shall continue the plan) will decide the point. I should state that the requisite inflammation is attended with the ordinary symptoms of pain, heat, swelling, some redness, and some constitutional affection. There should be, I think, some affection of the pulse, some indication of febrile action, before the seton is withdrawn. The threads may then be removed; I believe you then will have excited inflammation enough to cure the disease. So that it is not whether the seton has remained in ten, twelve, or twenty hours, but whether the requisite inflammation is produced. Perhaps twenty hours is about the average time for the seton to remain.

"This plan of exciting inflammation by a seton will answer your purpose in various other cases, as in ganglions, when you cannot get rid of by bursting them under the skin, or by puncturing them with a surgical needle, and which it would be dangerous to remove. Enlarged bursae may be treated in the same way. The surfaces of these cysts being thus brought into contact, you obtain adhesion. I have done it repeatedly, and in hydrocele of the thyroid gland. I was consulted respecting a large swelling which was evidently situated in the thyroid gland, in a lady. Many plans had been adopted but without success; I had no inducement therefore to go through the same routine of remedies. It appeared to me quite clear that there was a cyst containing fluid. I accordingly introduced a canula, by means of a trocar, for the discharge of the fluid. I then carried a seton through the cyst, and allowed it to remain till what I considered a requisite degree of inflammation had been produced. The result shortly was that she became completely cured, and she remains well to this day."

LONDON MEDICAL SOCIETY.

Mondan, Nov. 16, 1835.

MR. CLIFTON, V. P., in the Chair.

TREATMENT OF BRONCHITIS.

MR. ROBERTS, the secretary, read a paper on acute bronchitis. He observed that bronchitis was not named by authors to the present century, and that it had not been for the purpose of

ethoscope, the disease would have remained undistinguished even up to this time. In infants he considered it not unfrequently complicated with pneumonia, and sometimes terminating in croup; or, on the other hand, croup terminating in bronchitis; the last of which, he thinks, is the most common. The functions of respiration were more prominent in bronchitis than in pneumonia. As to the severity of the disease, he was convinced that practitioners would generally do well to leave nature to accomplish the cure her own way, for the more they attempted to do, the greater number of patients they lost. In the young, if left to nature, not more than one in fifty cases would be lost. When he first entered the profession, he adopted the depleting treatment of the day, and the result was, that he lost nearly every patient. Fortunately for his patients, one child fell under his observation which got well without any treatment; and a second case recovered through the administration of wine. With these examples before him, he was induced to adopt more simple remedies; and since then, his mode of treating bronchitis in young children had been altogether as successful as it was before unsuccessful. His remedies were of the mild kind, but the greatest benefit he had derived was from the *vin. sem. colch.*, combined with, or followed by, purgatives. The effect of colchicum in bronchitis affecting children was very remarkable. If given when the child was apparently dying, relief followed in a few days, and the cough, frequently so troublesome, was arrested by it sooner than by any other remedy. In old people he employed bleeding pretty freely, followed by purgatives; and as in them it was a severe disease, he would recommend a combination of the two. The advantage of purgatives was made known to him through the mistake of an errand-boy, who carried some powerful aperient medicine, which was prepared for another patient, to one who was suffering severely from bronchitis, and on whom it operated copiously, and effected a complete cure. He objected to blisters, and was surprised that practitioners had so great a predilection for them in this disease; and opium he looked upon, if not as a fatal remedy, certainly as always injurious. He had also found expectorants prejudicial, for the expectoration was profuse in the first few days of the attack, but as the inflammation progressed, the secretion ceased, and it was vain to attempt to reproduce it by expectorants.

Dr. CROWE begged to remark, with reference to the interesting paper which had been read, that Mr. Robarts must have understood Cullen, when he implied that opium had not been mentioned by that author. Mr. Cullen decidedly spoke of opium, and described the symptoms of its use. Mr. Robarts had

done, Cullen himself saying, that writers called the disease by different names. Laennec preferred the term of catarrh to that of bronchitis; and to prevent it from being misapplied to designate a simple cold, he divided it into active and passive. Dr. Duncan also had described the disease, and admitted that consumption might supervene thereon.

Mr. JONES believed that the first author who had used the term "bronchitis" was Franks.

A VISITOR differed in *toto* from Mr. Robarts, for, in his practice, he had found the utmost service from calomel, *ippecacuanha*, and tartarized antimony, and leeches, in bronchitis; few cases he thought admitted of the warm-bath, except at the commencement of an attack.

Mr. HEADLAND believed that the proper mode of treatment would be less disputed, if we understood what was meant by the term "inflammation." He agreed with Mr. Robarts, that if the antiphlogistic treatment was pushed far in children, failure would generally result, the lungs in children not having the power to withstand powerful remedies. Calomel also had failed to be with him so decided a specific as many practitioners professed to find it. When the condition of the lungs arose from a congested state of the circulation, accompanied with a quickness of pulse (query slowness?) and a difficulty of breathing, stimuli would be found beneficial. In old people, he would recommend a more moderate treatment than that advised by Mr. Robarts, and would also give opium and calomel, and he would strongly recommend mustard poultices to the chest.

Some other gentlemen also gave their opinions on the treatment, not a whit less contradictory as regarded the principles and the remedies, and we therefore refrain from recording anything farther on the subject on this occasion, excepting so far as to say that bronchitis was generally considered, by all the speakers after Mr. Robarts, as demanding more care than nature herself was disposed to give to it.

Mr. ROBARTS briefly replied, urging reasons for still retaining the opinions expressed in his paper.—The meeting was then adjourned.

Monday, November 23, 1835.

Dr. WHITING, PRESIDENT.

RINGWORM.—DEATH FROM MORISON'S PILLS.—ARTIFICIAL FEATURES.

The time was very much occupied this evening in discussing the subject of ringworm, which was incidentally brought forward by Dr. LEONARD STEWART, who has by accident found three or four obstinate cases of this disease yield to the appli-

cation of a weak solution of opium* (one drachm of the tincture to a pint of water) after various other remedies had been uselessly tried for some months. No constitutional treatment was required. Dr. Stewart asks, Is it an effectual remedy, or accidental? Very little notice was taken of the remedy by the members, who admitted that the opium had not over-acted its part, for some cases got well without any treatment, others certainly from merely being sent into the country: and others, again, from being treated by leeches, and with evaporating lotions.

Mr. CLIFTON strongly recommended a wash composed of ʒss of the strong sulphuric acid, with ʒi of water, which he (Mr. C.) believed, after an experience of twenty-three years, possessed advantages over all other remedies. The nitrate of silver would insulate the disease, and destroy its contagiousness. He regarded every species of the disease (except *porrigio favosa*) as purely local.

Mr. HEADLAND said, that experience had convinced him that ringworm arose from a depraved condition of the fluids of the body, which being corrected, local treatment might then be used with advantage. He named the juice of lemons as a remedy, in doses of half an ounce, or more, taken internally. The effects of the remedy on the altered fluids, in conjunction with the local disease, were commented on. Some remarks were offered on sea-scurvy, but we have not space for further details.

Dr. JOHNSON informed the Society that a lady whom he had visited, had that day died from taking Morison's pills. When he (Dr. J.) was sent for he was from home, and on returning in less than three hours afterwards, he found a second message stating that she was dead. On Friday last, the lady purchased two boxes of "Morison's mild pills," of which pills she took eight, ten, and fifteen a day, without effect. A stronger quality were then had recourse to, and the result was fatal. The symptoms produced were, violent hypercætharsis, inflammation of the bowels, coma, fever, and death.

Mr. CURTIS presented a man to the notice of the Society, of a tolerable appearance, who wears a "false nose," a "false palate," and "false spectacles," who before the poor fellow's ingenuity had suggested these contrivances, was said to have been a most deplorable-looking object. The nose was carved from box-wood, and fixed with firmness into the frame of the spectacles, the use of which latter would not otherwise be required; a thin fold of cotton forms the artificial palate, but a small portion of the natural palate remains, and much assists the

adaptation of the artificial one; in the immense cavity occasioned by the entire destruction of the nose, he places a piece of sponge, which absorbs the moisture, and considerably assists articulation, which (when his "artificials" are arranged, which is almost momentarily accomplished) is distinct and loud, but without them no utterance appeared nearly inaudible. His made-up appearance seldom is detected.

After the adjournment, most of the gentlemen present added their names to the address of condolence to be presented to Mr. Kingdon.

WESTMINSTER MEDICAL SOCIETY.

Saturday, Nov. 14, 1835.

Mr. RICHARD QUAIN in the Chair.

MINERAL MAGNETISM.

Dr. SCHMIDT (of Berlin) was announced to read an essay on the application of mineral magnetism for the cure of various nervous diseases. The subject occupied attention during the greater part of the evening, and was adjourned finally to another meeting. In introducing his subject the author premised that mineral magnetism was totally distinct from animal magnetism, and that the magnetic influence acted solely on the nervous system. He then gave a history of the science, and described the doctrines of all authors who had advanced opinions on the subject. In accounting for the magnet having fallen into disuse, he said it arose from an opinion that the cures effected by it were not lasting, the reason of which was that the magnet was never applied systematically, and only by way of experiment. To accomplish cures, powerful instruments must be employed; for the minor magnets could only remove trivial diseases, and even in them frequently failed. Of the instruments employed three were named; first, the *horse-shoe magnet*; second, the *magnetic staff*; third, the *magnetic plates*. The curative power of the first is in direct proportion to its power of attraction, and that is the chief instrument employed to perform magnetic cures. The five-fold *horse-shoe magnet* consists of five simple horse-shoe magnets horizontally placed, and closely adapted one to the other, the centre magnet being the longest and thickest, the others each gradually diminishing in length and thickness, the arrangement being thus made in order that the power of attraction might fall in the centre, or, rather, that each magnet might not be exerting its influence on the needle at the same time separately. The power of attraction then would be as $5 \times 5 = 25$, instead of $5 \times 1 = 5$. The power of these magnets is such that

* The tinct. opii, sometimes used pure, at other times diluted, is an old and occasionally an efficacious remedy in some conditions of *porrigio*.—*Rep.*

10 to 120 lbs. Larger magnets are only necessary in extreme cases, or where it is desired to transmit the magnetic fluid to interior organs, as in cases of deafness, for then magnets of from 200 to 500 lbs. power of attraction must be employed; of which power he (Dr. S.) has constructed some. The magnetic staffs are only applicable in cases of toothache. The magnetic plates are used where the horse-shoe magnet cannot be applied; as when magnets are required to be fitted to any part of the body. For the treatment of diseases with either kind, either powerful instruments were used from time to time, or the continual influence of magnetism was employed, by the patient wearing small magnets for some time on the part affected. The former is either topical or general, and employed in a certain order, with one or two poles, and with one or two instruments, always following the course of the nerves in passing them. According to the theory hitherto followed, it is supposed that the "friendly" poles as they are called, ought to be placed opposite to each other, in order to lead a magnetic stream through any part of the body. The reverse he (Dr. S.) would prove to be the fact. (This was demonstrated with a sheet of cartridge-paper placed between the magnets and some iron filings, and with a bar of soft iron placed between the magnets.) For the application of magnetism, the patient may be placed in any position. If the eyes are to be operated on, the magnet is fixed for some minutes on the eye itself, and then passed several times across the upper and lower edges of the eyelids, commencing at the corner of the eye; and then several times from the forehead downwards, in such a manner that both eyes are touched at the same time. Sometimes the desired effect is not produced until the poles have been changed several times. For deafness the patient is seated between two magnets, so that the poles exactly fit in the plates of two small instruments, which are introduced into the organ. These instruments are made with an oval disc, one inch long, and half an inch broad, of soft iron, in the centre of which is fixed a black pin, one inch long, and one line in thickness. The operation may last from five to fifteen minutes. The magnet is then placed over both sides of the head downwards. For the toothache, he (Dr. S.) usually fixes the north pole first on the painful tooth, and if not relieved, then applies the south. If obstinate, he touches the gums with either of the poles, or passes them across the cheek, where the pain is most acute. The magnet should be first rubbed. The general magnetic treatment may succeed the topical, especially if the patient is nervous. The last division of his subject was devoted to the effects of magnetism on the unhealthy. As to the effects we need simply say, that

until he proved to the contrary, mineral magnetism, Dr. Schmidt said, was always declared to have no influence on healthy parts. Secondly, On the sick, magnetism is either soothing or exciting. Dr. Becker says, "Very often the patient considers that he has no sensation at all from it, but generally in the course of time, he experiences an effect from it." The sensations are, with some slight modifications, the same in all cases, viz., cold, warmth, increased sensibility, and pulsation, and numbness and insensibility in the part affected. These sensations, except the last, increase gradually, and then become weaker, until at last they disappear entirely. Dr. Schmidt concluded his paper, by saying that the effects of magnetism appear very often instantaneously. That they are not local, and that the diseases in which magnetism exerts a curative power, are those in which the sensibility or mobility of the nerves is heightened, or where the nerves are over-excited, as in tic-douloureux, headache, &c.; in spasms of the stomach, palpitation of the heart, hooping-cough, epilepsy, and convulsions; or where in the nervous system there is a want of action. Also, in some diseases not purely nervous; as in rheumatism, gout, suppressed menstruation. During the catamenia, or during pregnancy, it must not be used. Lastly, The doctor said that it was his conviction, that magnetism deserves a preference over all other remedies, in the diseases above enumerated. At the end of his Essay, Dr. Schmidt read an extract from *Hufeland's Journal*, for September last, speaking in commendatory terms of the science of magnetism. Dr. Schmidt then showed that the power of a magnet might be given to iron, or destroyed in a few seconds, a fact which was first made known by Dr. S. The process of destruction consisted in passing down the poles of one magnet, against the like poles of another magnet, commencing at the curve of the instrument. To reproduce the power, the poles were reversed in the passing motion, commencing also at the curve. Dr. Schmidt attached considerable importance to this experiment, for he says that when the power of the magnets becomes deteriorated, it is easily restored; and failure, which must frequently before have attended its application for the cure of diseases, could now be readily obviated.

Saturday, November 21st, 1835

Dr. ADDISON, President.

MINERAL MAGNETISM.

The subject of mineral magnetism was again introduced this evening, with much amusement, though not with much profit, and the discussion was closed with an intimation from some of the members, that

turn which it had taken was not consonant with the objects of a medical society. Dr. SCHMIDT, of whose talents it was impossible to avoid forming a favourable estimate, and who addressed his audience in the English language with a correctness which many speakers of our own nation might be glad to reach,—recommenced the subject by repeating some experiments, concluding, however, rather abruptly, and leading the discussion into a direction which lost for magnetism its chief claim on the attention of the Society. One experiment was designed to prove the discovery of Dr. Schmidt, that more magnetic power exists between the north poles of two magnets (a space intervening between them) than between the south poles, and that therefore in employing horse-shoe magnets on a limb, it was erroneous to oppose, on each side of the limb, a north pole to a south, and a south pole to a north, as the remedial process had always hitherto been performed, and always, consequently, with less success than by his (Dr. S.'s) mode. Testing this statement by experiment, the result seemed to bear witness to the correctness of the allegation.*

The experiments called on his legs Mr. Bird, who gave some designation to them which Dr. Schmidt did not consider very courteous. Considerable disputation resulted, for Mr. Bird denied the correctness of almost every proposition of Dr. Schmidt, and then, between various parties, began a series of not very obvious, or very conclusive, or very well-explained experiments with magnets and iron filings, accompanied by diagrams on a black board, all, too, so purely theoretical, that a *moral*, only,—which there is no need to explain—could be drawn from them. Yet the exhibition was tolerably entertaining, and might, had the philosophers been better agreed as to first principles, been useful to a majority of the audience, of whom Dr. Johnson afforded a good specimen, when, with rather unhappy look, he remonstrated, at the close of two hours, on the time of medical men being occupied so long on the mysteries of "north poles" and "south poles," magnetism by direct procedure, and magnetism by induction. "Let us know," he prayed, "what diseases magnetism will cure. We care not what influence it exerts over mariners' compasses, or bunches of keys, or steel dust."

Mr. Bird declared, as we have said, that Dr. Schmidt's proceedings were all "flimsy," and pronounced the chief results to be the

simple results of magnetism by induction. Mr. Bird, however, was himself sharply hit at the knuckles by Mr. Everitt, who suddenly interfered, "In order to save the time of the Society, to remind the young gentleman that those who were better acquainted with the subject did not admit the truth of the positions on which Mr. Bird was basing the whole of his objections." Mr. Bird, in fact, was proceeding to prove that the relative quantity of the magnetic fluid at the positive end of a bar of soft iron, would be shown by the power of attraction exerted by it over particles of iron filings represented thus, $\times 3-2-1$; or, that in the horse-shoe magnet, at its north or positive extremity, the magnetic influence would be represented by $\frac{1}{2}$; at its angle or intermediate space by $\frac{1}{3}$; and at the south, or negative extremity, by 0. This problematic experiment Mr. Everitt sought to show was in direct opposition to the "indisputable fact," that if a bar of iron were divided into any number of parts, no piece or division of it would contain more magnetic fluid than any other, provided the size of each division or compartment was exactly of the same size as each of the others, and if the division be carried down ever so low, the fact would, he contended, still be obvious.

Mr. Bird met this charge by declaring, as he did on each other occasion on which an experiment or argument was used against him, that he regarded it as a beautiful example of the theory he himself wished to advance; but having stated the theory and the objection, we must be content, from want of space, without giving further details on this point. Mr. Bird apologized for presenting himself to notice, and stated his object simply to be to defend the reputation of several great men whose views were opposed by the theory of Dr. Schmidt.

A degree of interest was here given to the disputation, by the reply of Dr. Ritchie to a call from several members for his opinion on the points advanced, but we are compelled simply to say that that gentleman with much clearness developed the best-accredited views on some points in magnetism, commenting briefly on the theories expressed by previous speakers, which, however ingenious, he did not consider correct in many respects. Circumstances, however, which we cannot stay to explain, prevented the impeachment of Dr. Schmidt's views from being sustained. Indeed, the time and apparatus did not admit of experiments in any respect conclusive upon any important point under debate. At the next meeting the medical division alone of magnetism is to be canvassed, when the subject will most probably be concluded. We here observe that Dr. Ritchie's opinion was not of opinion that magnetism could be advantageously employed in the treatment of diseases, though he admitted that on one

* Dr. Schmidt also showed a method of obtaining the magnetic spark by means of a very simple apparatus, constructed as follows.—A piece of soft iron, round which a copper wire is twisted, the extremities being amalgamated with quicksilver, is placed over the poles of a magnet. On one is fixed a small copper plate, and the connection being then forcibly broken, the magnetic spark is vividly produced.

two very curious results follow the application of the galvanic battery. In justice to Dr. Schmidt, we may state that he appears to be perfectly candid and open in all his explanations relative to the "mysteries" of mineral magnetism as a remedial agent in disease.

MEDICO-BOTANICAL SOCIETY.

Tuesday, Nov. 24, 1835.

EARL STANHOPE, *President, in the Chair.*

SOME beautiful specimens of the acacia, catechu, manchean gambier; specimens of the greater and lesser cardamoms, and of the grains of paradise, this evening were exhibited as presents from Professor Martius, with a view of obtaining, through the medium of the Society, correct information as to their proper classification and derivation. Mr. Hiff and Mr. Battley also presented specimens, with a view to ascertain whence they were procured.

Dr. SIGMOND drew attention to a new sort of catechu, lately introduced into this country, which he said was superior to any hitherto imported, from its presenting a much larger quantity of tannin than the other species of catechu. The new species had been introduced by the cotton manufacturers of Manchester, who have found it yield a valuable dye. Dr. Sigmond then made some remarks on the different varieties of cardamoms. The medicine is brought from Singapore, but as that is a free port, it is difficult to ascertain its original locality. The other variety (samples of which, particularly fine, were on the table) is brought from Java and Ceylon. Professor Martius seems to think that the grains of paradise are in fraternity with the larger cardamoms; but Dr. Sigmond said, that whoever tastes the paradise grains, will, from its peculiar flavour, readily perceive the difference.

Mr. HIFF said it was impossible to arrive at a proper solution of Professor Martius's questions, until the different importers had been consulted.

Dr. RYAN also made some observations on the catechu and cardamoms.

A paper was then next read on the different barks of Guiana, forwarded to Dr. HANCOCK, who transmitted the paper to the society. A splendid branch from the castor-oil tree (*ricinus communis*), reared in the Society's gardens, the property of Mr. Gibbs, was presented, covered with seeds, and although grown in this country, it was as perfect as one of those sent from the East or West Indies. The capsules were exceedingly small, covered with rough spines, and were so arranged as to expel the seeds. Specimens of the castor-oil, pure and im-

pure, were also laid on the table, and some of the watery extract of bark, which Dr. SIGMOND (when alluding to the properties of different drugs) said ought to supersede the sulphate of quinine, for it contained "nature's own acid," and the gallic acid, combined with the alkaloid, without having to pass through the numerous manipulations of the chemist, which rather obtained educts than products. The Society was then adjourned.

ERRATA.—In reports of Medical Societies last week, at page 313, line 8, for *cancer* read as *exostosis*.—Line 33, erase the words between parentheses.—In note, at page 316, line 6, for *combined* read *uncombined*.

An Inquiry, Physiological and Pathological, into the Proximate Cause of Cholera. By PROTHEROE SMITH, M.R.C.S., Sen. Surg. to the Farringdon Dispensary. London: Bailliere. 1835. pp. 39.

To know the first tissue in which a disease commences, is not to know the "proximate cause of that disease;" nor does a knowledge of the first step which a disease takes, imply a knowledge of its "origin." To inquire into "the proximate cause of cholera," is, in reality, to carry research up to the identical cause of the first derangement of the earliest tissue affected. Over the cause of cholera we agree with the author that "a cloud of mystery hangs;" but from around the chief features of the disease itself the mist we think is now dispelled, and amongst those who have helped to clear away the vapours, we must rank Mr. Smith. The modes of treatment which are urged to cure the disease are as various as they seem to be, first, because so many medicines produce the same ultimate effects on the animal economy; and, secondly, because the profession do not choose to agree on the therapeutic details which their therapeutic doctrines might teach them. That the view we take of the "cause" of the disease is held by Mr. Smith himself, the following sentence demonstrates:—

"Mental disquietude, or atmospheric influence, often exists as an exciting cause of diseased action, producing effects on the sensorium similar to those caused by external bodily injuries, and often inducing more suddenly the results above enumerated, as is instanced by imbecility or death occasioned by fright or grief, and by epidemic disorders arising from miasmata and other like sources. Thus, even when the exciting

cause of disease is not cognizable to our senses, it often produces sequelæ more violent than the results of extensive corporal injury."—p. 10.

He puts aside the cause of the disease in order to discuss the conditions of body under which its phenomena occur.

"I proceed to the inquiry of those conditions under which occur the various phenomena constituting the disease under consideration. Of the ultimate cause, or first principle, from which cholera results, I shall not attempt to offer any other solution than that it depends, and is consequent, on the will of the Great Author of Nature. . . . I therefore leave the subject to those ingenious speculators in mysteries whose time is their least valuable commodity," and shall proceed to treat of the proximate or immediate cause from which the evidences or symptoms of the epidemic cholera directly proceed."—p. 11.

The terms "proximate," "ultimate," "first," "exciting," and "immediate," are prefixed to the word "cause," in medical discussions, in a manner which questions in the exact sciences will not allow. But the error is great, and we constantly find mischief to arise from the misapplication of these adjectives in medical writings. Any morbid change produced in the body, even the very first and minutest of a chain, is the disease itself, or a part of the disease, and not the *cause* of the disease, either proximate, exciting, ultimate, or immediate.

Having stated our own view of the title, we proceed to give some account of the author's object in the contents. Mr. Smith divides the disease into the usual three stages, which he discusses in a plain and conclusive manner. The "preliminary symptoms," he says, "evidently indicate a disturbance of the *prima viæ*, and the peculiar action of the exciting cause is clearly that of morbid impression on the follicular apparatus of the intestines." Taking the liberty ourselves of condensing his views, he proceeds to say,—

"Conscious of the attack, an effort is made at the brain to resist the assaillant, and an inordinate action is established in the alimentary canal, while the heart's action is greatly increased to supply the

* These are the very gentlemen whom cholera demands. With more time there would be fewer mysteries. Which, indeed, are now the "*mysteries*" in cholera, if the real *causes*—proximate, exciting, or what you will—be not?—Ed.

means for the extensive alvine discharges. This constitutes the first excitement, or preliminary fever, in which bold blood-letting is the only effectual remedy; but these symptoms precede the complete seizure by so short an interval, that the application of means is sometimes precluded, and some have even doubted their existence. The increased exertion continued in the sensorium, would be alone sufficient to induce collapse, from the inertia following unusual exertion of any function; but this sequela is accelerated also by a rapid loss from the very fluid on which nervous energy depends. The immense defluxion from the intestines robs the blood of its saline and serous particles, and renders it thick, tenacious, and unsuited to circulation, necessarily requiring an increase of power in the heart to propel it through the usual channels, supposing they were of sufficient caliber to admit this thickened fluid. The result is, want of pulsation in the extremities, cold surfaces, deficient pulmonary circulation, and, consequently, imperfect decarbonization of the blood, suppression of the renal functions, and consequent continuation of the urinary bladder. The voluntary muscular contractility of the body, now altogether uninfluenced by the nervous power, becomes violently and involuntarily active and irregular, which accounts for the peculiar characteristic of this stage of the disease. The continuance of these morbid actions frequently carries off the patient. There is a cessation of muscular spasm consequent on paralysis, from vascular engorgement, or effusion into the cavities or substance of the brain, which, from the heart being gorged with blood too dense for distant circulation, is overcharged; a rous, or sanguineous effusion, or apoplexy, closing the scene. When the patient recovers from this state, the third stage results, usually presenting all the concomitants of *typhus*, a disease too well known to need description. Thus we have successive resulting states, which have their origin in derangement of the *prima viæ*. In support of these views, I will cite a few post-mortem examinations, which, I think, will substantiate my opinions, inasmuch as they all evince great cerebral disturbance of the brain."—p. 13 16.

We have already so many autopsies of cholera patients on record in our Journal, that we shall withhold extracts from this part of the pamphlet.* Suffice it to say that

* With one exception.—In the last case recorded the author says, "The fingers crackled on being straightened, which last circumstance was thought by M. H. Grand a peculiar characteristic of cholera," and he adds, "I might recount other cases, but think the few already cited show the frequency of this symptom."

those "post-mortem" which the author—who has had excellent opportunities of observing the disease—has cited from his note-book, justify the views he has expressed. Relative to his own plan of treatment the author says,—

"The plan most in accordance with my views, has, in general, proved of most avail. Mr. Kennedy, in his valuable work on cholera, asserts, that his plan of remedying this malady has proved more successful than any he has seen practiced, and the evidence of the mass of authors on this subject has a similar tendency."—page 28.

The plan of Mr. Kennedy is well known. The details of Mr. Smith's plan, are fully given in his pamphlet, which contains the result of much observation in a very small compass. Of his experience he says,—

"I availed myself of an opportunity for extensively observing the morbid appearances of this disease in the autumn of 1832. Through the introduction of Mr. Kiernan, I became acquainted with M. Halma Girard, who was deputed by the faculty of Paris to investigate the nature of cholera in London, previous to its appearance in France. I assisted this gentleman in his post-mortem examinations, and collected accounts of a large number of cases."

THE LANCET.

London, Saturday, November 28, 1835.

Within a very few years the City of the metropolis of England not having become an University, under the sanction of an Act of Parliament, or the authority of some royal decree, up to close of the year 1835, will be considered one of the most extraordinary circumstances that can be related in connection with the history of the literature of this country. It does not even appear that, until a very recent period, the question of establishing an University in the metropolis, has ever been mooted by persons whose character could give weight to their sug-

gestions. When the project was first announced for founding the University which is now proceeding in its successful career in the northern part of London, the projectors were made the objects of contemptuous ridicule, by the members of that wealthy and influential party which had so long directed the destinies of the empire. Entirely destitute of arguments which could be urged against the philanthropic scheme, the opponents of the measure resorted to every species of slander which malignancy could invent, in order to deter the subscribers from proceeding in the great national work in which they had engaged. It was pretended, indeed, that the idea of founding an University in London, or, rather, of establishing colleges in London, which should confer on the metropolis itself the title of "an University," had originated in a desire to offer an opposition to the national Universities of Oxford and Cambridge. The pretence was the off-spring of falsehood, bigotry, and folly. The founders of the University were stimulated by no such unworthy motive. On the contrary, there were to be recognised amongst them men of the most distinguished and exalted attainments,—who were indebted for their learning, and the multitudinous pleasures which they had derived from the cultivation of their minds, to those splendid institutions which it was alleged to be their object to destroy. In the secure possession of a vast amount of real property, sustained and invigorated by a system of electing the ruling authorities, so liberal in its character that it is restricted only by the number of the Fellows belonging to the Universities, what could such establishments fear from competition? Nothing. But whatever benefit the members of those institutions can hope to create from the more wide diffusion of learning and knowledge, must arise from the stimulus of honourable rivalry amongst congregated masses of the literati of the empire, and, in reality, from the exercise of that just and useful invention alone.

The founders of the *University of London*, in carrying their plans into execution, performed a labour which was likely to be followed by advantages of an immediate and not of a posthumous description. They hoped to outlive the successful commencement of their labours, and were not so vain or so foolish as to attempt to enter into a contest with the ancient Universities of Oxford and Cambridge, immovably fixed as were the latter, on solid masses of treasure, and renowned as they had become throughout the world, as the most celebrated establishments of learning in civilized Europe. There was no desire to circumscribe the sphere of advantages attaching to a collegiate education, which had been created by those venerated seats of learning. On the contrary, the promoters of the great academic enterprise in London sought to widen that sphere, to multiply the opportunities of learning, and to afford to some thousands of the youthful inhabitants of England the means of acquiring, on cheap and accessible terms, a first-rate education in literature and the sciences. The friends of Oxford and Cambridge, therefore, had no legitimate ground of suspicion or jealousy on that occasion, and it is quite certain that the gentlemen connected with the ancient universities, who are the most exalted from the extent of their learning, and command the greatest share of respect for those qualities which most distinguish at once the philosopher and the man, became, at an early period, the advocates of the new scheme, and ardently did they desire that the efforts of its supporters might be crowned with success. Without having received the slightest assistance from the Parliament or the Crown, the claims of the *University of London* to distinction have taken a firm hold on public opinion, and, under difficulties which it may be considered are now surmounted, the institution has passed through a seven years' ordeal, preparatory, we trust, to running a splendid career of national usefulness.

Under circumstances of so favourable a character, we do not expect the proprietors, at their meeting, which is to be held on Wednesday next, will enter into any discussion or approve of any measure, which can lead to an inference with the thinking portion of the community, that the interests of the University could be advanced, that its reputation could be increased, or that the sphere of its usefulness could be enlarged, by obtaining from the Legislature or the Crown any privileges of a strictly exclusive or local nature. The professors are too generally distinguished for their acquirements, and they must be rendered too independent by their industry, to imagine that the institution could derive any advantages from aids of so dubious a character. Nor must it be forgotten that when the project of founding this University was first opened to view, the sympathies of the public were wooed in its favour, by a reference to the principle of exclusiveness, which had so long shut out dissenters from collegiate honours in the Universities of Oxford and Cambridge. Let not, therefore, the new institution attempt at the end of seven years to give strength to an abuse which it was designed to destroy. The principle of exclusiveness cannot exist, certainly it cannot flourish, in the new metropolitan institution. London itself must become a regularly-organized and acknowledged University in the British Empire, and the great establishment now styled the *University of London* will, we are convinced, throughout many succeeding ages, take the lead under the name of "UNIVERSITY COLLEGE," or some other title, as the most liberal of those academic establishments, by means of which the fame of the University of the British empire will be nobly sustained. It will constitute at once the chief pillar and the brightest ornament of the metropolitan universities, and the names of its founders will be placed by the future historians of the literature of England, amongst those of the noblest factors of the human race.

Whatever may be the intentions of some of the proprietors in convening the meeting Wednesday next, we may take this opportunity of informing them that so far as the medical department of the University is concerned, it is not in the power of the Ministers of the Crown to confer upon gentlemen who may be educated in that department of the University, any legal advantages in connection with the practice of medicine. Acts of Parliament present insurmountable obstacles to the granting of any such concessions. It would not be audacious, therefore, to press on the attention of the executive government, questions of such a nature, because, although it may be desirable on the part of some individuals to restrict the view of such subjects within the walls of one institution, it is quite evident that if the matter be once taken up, it must be carried out into a far wider range, and then the value of university distinctions may go far towards being sacrificed by the immense number which it would be found necessary to confer. At present, the University, especially in its medical department, stands in a pre-eminently exalted situation, and under such circumstances we should be sorry to see it become the object of an uncertain and hazardous experiment.

At page 350 we have given insertion to the effect of Mr. G. BERY, relative to the proceedings at an inquest held a few weeks since at Farnham. The contents of the letter indicate little that is favourable either to the judgment or the temper of the writer. The subject, however, has now assumed a somewhat serious aspect, and in the absence of Mr. BERY's disposition before the Coroner, we shall refrain from saying another word on the main question at issue.

With regard to that deposition, Mr. BERY will, of course, be glad to hear that we shall publish a *verbatim* transcript of it, by moving, on the next sitting of Parliament, for a copy of the evidence taken at

the inquest, as well as of the verdict of the jury. We trust that this announcement will be satisfactory to every person who is anxious to obtain the truth, the whole truth, and nothing but the truth, touching the subject under investigation. It may be very agreeable to the feelings of Mr. G. BERY to exhibit his deposition to the clergyman at Farnham, and other respectable friends in that town, but we shall not be satisfied until it is laid before the members of the medical profession. When we have obtained possession of these documents, we shall devote a few pages to the discussion of the important subjects which the inquiry involves.

In giving insertion to the letter of Mr. TARNETT (page 348), we regret that we cannot find space also for a copy of the petition of that gentleman, presented last session to the House of Commons. Mr. TARNETT will, of course, best consult the independence of his character, and the purity of his motives, by refraining from entering into any contest with his brother governors. It is his duty at once to refer the Committee of Almoners to the office of the charity Commissioners who are now sitting in Great George-street, Westminster. It is time that some inquiry was made into the affairs of *Christ's Hospital*, for it appears, from the official accounts of the hospital of the expenditure of one year,—from December 1833 to December 1834,—that the monstrous sum of 10,237*l.* 1*s.* 4*d.* was swallowed up in that institution in "salaries" alone!

KING'S COLLEGE, STRAND.

In consequence of the small number of medical students who attended this school last year having been diminished less than one half in the present session, several of the eminent professors of the establishment have been anxiously deliberating what course to pursue as regards the future, when Mr. MAYO, the anatomical teacher, was induced to write to Dr. HAWKINS, the celebrated professor of the practice of physic, explaining

to him the importance of his retirement from the school, and the necessity of appointing a man of still greater eminence to fill his chair, as one of the principal means of reviving the medical department of the decayed institution. HAWKINS, with a pride which did him honour, rebutted the charge, and for answer returned to Mr. M. a copy of his own letter, merely changing the name of "Hawkins" for that of "Mayo;" whereupon the teacher of anatomy, with an equally honourable high moral feeling, sent a letter to the Council, containing a resignation of his professorship, which, as he anticipated, was not accepted, so that the school continues to be embellished with two names equally high in the page of medical fame! On another occasion we shall publish the letter.

Dr. WINSTER has been used very ill at this institution. We are authorized to state that he has suddenly had notice to quit the chair, Dr. PARIS having considered it, after all, too important for his worldly views, to let slip the opportunity of getting into the Strand.

INTERCEPTED LETTER.

"DEAR DOCTOR MACMICHAEL,—You know me sufficiently well, fully to comprehend the salutary influence which a retreat from the busy "haunts of man" to a sequestered spot like this, must have produced, not only on my enfeebled frame, but on my fatigued and harassed intellectual functions; I feel that at my advanced period of life every year gives my constitution a *shake*, and I am sensible that my mind is now much longer in recovering its powers and its wonted vigour,—that there is a greater want of elasticity about me—than when you first knew me. However, I mean not to complain. I am thankful to a munificent Providence for numerous earthly blessings, and the most earnest wish of my heart now is, to end my days in contentment, and to die in peace with all men!

"This delightful abode affords me, I do assure you, every possible means of renovating my physical frame, and of elevating my drooping spirits; and though I confidently trust that I shall gradually be restored to perfect health, yet it must, I fear, require some time to restore me to my professional labours,—and what, my dear friend, is my fondest wish, to be able to use my best efforts to preserve our venerable institution! As to my *private* practice, you and other of my friends, I am well aware, are decidedly of opinion, that the ample fortune I enjoy ought to make me careless about receiving any more fees. I am, however, firmly convinced that if I were to show less eagerness in getting patients, and to pay

them fewer visits when my attendance solicited, I should be less esteemed, and should lose my consequence and importance in the estimation of society. I should then be much less able to support the sacred cause I now uphold, by exercising the power which I possess over many of the most enlightened and elevated individuals, both of church and state,—an influence which all admit I have on many occasions judiciously and successfully exercised, for supporting the dignity and reputation of that elevated branch of the profession to which we both have the honour to belong!

"The time I have spent here in reflection, and in deliberating on public affairs, has *not* altered my opinion on one single point. No man in his senses can doubt, that every one of our sacred and venerable institutions is either trembling, or absolutely tottering; and I often reflect on the truth of an observation of Pazzo di Borgo, 'that the British constitution is formed of such a flimsy mass of materials, that if an attempt be made to alter or repair any one part of the edifice, the whole must be pulled down and built anew.'

"But however determined I am, as you know me to be, to stick to the last rafters of the wreck, I cannot conceal from myself the deplorable state of all our medical corporations; I will not even except that of Pall Mall East, and I do not see the possibility of any system of legislation altering the condition of the medical profession, whilst the present system exists. It would be infinitely more politic in the reformers, as Mr. WASHINGTON contemplates, to overthrow the whole existing colleges, and build up on their foundation one system to regulate the medical profession as a great whole.

"Nothing has appeared more incongruous to many intelligent and virtuous men who have interested themselves in the proceedings of the Parliamentary Committee, than the undeniable fact of all our charters and laws being violated and neglected, the members of each of the institutions acting in all respects the very reverse of what their laws direct. These are to me insurmountable difficulties in all my conferences with my great political friends, who even taunt me with the fact admitted in the "Evidence," of a large portion of the income of the members of our venerable College, being derived from the practice of midwifery,—the vilest part of surgery, which the pure surgeons will not condescend even to be supposed to know anything about, whilst those very *pure*s have the effrontery to confess that they practice *physic* as much as surgery. Another dilemma, from which I cannot extricate myself, is, that of living with any degree of plausible appearance of reason, honesty, and subordination,—then, whose care the

ty is placed, both high and low, rich and poor, should be considered the *lowest* grade of the profession, whilst they must, necessarily, possess as much knowledge both as a pure physician and a pure surgeon put together. This is so contrary to the usages of all other professions, that it is quite indispensable. In every other department of life, when rise in the estimation of society in proportion to the extent of their knowledge.

"Be all these things as they may, *our* position as a chartered body is evident, and we cannot act with more consistency, honour, and benefit to our own interests, than by using every means to uphold all our ancient privileges, taking care to humiliate all those to whom we grant *licenses*. It was, indeed, gratifying to observe that the few Licentiate who signed the last appeal to Parliament, were so low and disreputable a squad,—a parcel of Scotch *Dubs*, some of whose names I don't think I ever before heard of.

"It will be time enough, by-and-by, to arrange what kind of *reform* it may be wise and politic to bring before the College, however little, if any be intended. We must keep constantly *talking*, like my esteemed friend Sir Roderick PEARCE, about a '*rational reform*,' and ward off the evil hour as long as we can; and I do assure you, my dear friend, that I feel it a great consolation, to hear that there is not one *Fellow* who in his heart desires anything like a *radical* change. They are all, I am persuaded, to a man, *aristocrats* at bottom, and only make use of the filthy slang of *liberalism*, that they may pull me down, and mount up their own dear selves on the ladder of power. You will, I am sure, do me the justice to admit that these opinions are correct; and no wonder that it should be so, if you will but for a moment consider what could have ever induced them to be at the expense of the *rigmarole* process of term-serving at Oxford and Cambridge, and after all be obliged to go to some Scotch university, as I did, to learn their profession. Nothing but an inordinate love of *grade*, or whatever you choose to call it, could have induced them to submit to such measures; and, after having done so, who is the man amongst us to sacrifice the privileges thus acquired, and become a *leveller*? It is just as impossible for a camel to go through the eye of a needle, as for a *Fellow* to place himself on an equality with a *Leucate*!

"Matters are going on at Windsor much as I expected. They never send for me now-a-days, but I think it right to pay them a visit on my way to town when I go to see such patients as want me. The QUEEN has certainly improved in health, and all her features are much less red since she has been pursuing the homœopathic system. The German doctor has, I am informed, succeeded, after having

remained at Windsor nearly a couple of months, under the pretence of watching the effects of his millionth part of a grain pills. I think we need not talk about the prerogative of our College to suppress quackery after this.

"I take it for granted, that there is very little going on in the way of practice at this season of the year. But indeed I am well aware of the fearful changes that have already taken place, and which, I fear, will continue to go on in the profession, every one of its departments suffering from the changes of the times. We must all be contented to work on more moderate terms, for by keeping up the prices, business has already gone nearly all together out of the hands of *physicians*. A few days before I left town TUPPER told me that the top-apothecaries had also great cause of complaint. 'In the good old times,' said he, 'when I sent in an account of 50*l.* 19*s.*, I should be paid by a check for 100*l.*,' but since the Reform Bill has passed, in place of the 100*l.* I receive only 50*l.*, the 19*s.* being actually deducted! Most families, too, keep a medicine chest, and they sometimes have the impudence to ask me to 'weigh out a dose for them.' *Tempora mutantur!* The apothecary also complains sadly of the '*physician-accoucheurs*,' as they designate themselves, certainly a curious species of physicians,—a kind of non-descript animal, which we ought never to have admitted into our College. Those hermaphrodites do everything; they put the ladies to bed,—inoculate the children,—scarfify their gums, draw their teeth, give them clysters,—cure the husband of gonorrhœa,—bleed,—and, in short, do things that even the lowest of the "*subordinates*" will not do. The chemist is no less hurtful to the legitimate and pure physician. Those vagabonds take care not only to sell drugs, but to *prescribe*, which is most infamous, and must be put a stop to. The whole profession, indeed, seems to me to be in a state of revolution, so that I do not know well what is to be done, though, at the same time, placed as I am at the head of the profession, I am compelled, by every moral feeling, to support that system of medical government which has worked so well for me.

"The weather here has been delightful, and I employ myself busily in making improvements on my beautiful domain, and in the society of my neighbours. There is a set of sporting men about here, for whose conversations I have generally no relish; but there are also some enlightened members of the established church, and a few well-educated squires, whose society I like. I amuse them by repeating the more imposing passages of my *orations*. There is very little female society within my reach; these I amuse in *other* ways. Old Lady N—— often pays me a visit, and as she does

not understand the classics, I entertain her with all my antiquities, and an occasional bit of court scandal!

"I ride about a good deal, on an old pony, who is both blind and broken-winded, and neither shys nor gallops off with me, but fatigues me sufficiently to give me a good appetite. My groom is very amusing in the account he gives me of the wonderful effects of all his nostrums, but not a 'subscription' (which is his name for a prescription) will he reveal to me. One day I said to him, 'What is that stuff, John, you are rubbing the mare's leg with?' To which his only reply was, 'It is some things that I mixes together.' There is no doubt that the mystery which these grooms make about their stuffs, as they call them, and their *humoral* pathology, suits the minds of most people much better than one of my profound classical disquisitions. Well do I recollect my beloved friend and ever-to-be-lamented sovereign, GEORGE the Fourth, mimicking the manner and strange sayings of a royal groom who used to afford his majesty the greatest amusement. GEORGE was fond of a joke, and was so perfect a mimic, that had he been *compelled*, I have no doubt that his appearance on the stage would have been as brilliant as, on the throne, he was magnificent. Nobody with whom his majesty was ever acquainted, escaped his powers of imitation, and I perfectly recollect my quondam friend WARDROP telling me—which he did in the most delicate manner—how the KING could, with the utmost accuracy, imitate my voice, my mode of expressing myself, and, above all, how fortunate he was in mimicking what I had always understood to be my *forte*.—my manner of coming into a sick room, and expressing, by my countenance and gestures, the utmost anxiety for the patient, and the deep interest I seemed to take in the minutest details of the case.

"I continue to take much pleasure in attending to my farm-yard, and although the markets are very low, I do not think the farm will be a losing concern to me this season. My fine beef has brought me from 3s. 6d. to 4s. per stone (sinking the offal). Mutton brings from 3s. to 3s. 6d. I am celebrated for my pork. Nothing, in fact, agrees better with my own stomach, and I have been feeding my domestics so much upon that food lately, that when I ordered my old-fashioned confidential bailiff, the other day, to slay a famous pig of the Chinese breed, he jocosely observed 'Law! yer 'honour, we have bin eating such a lot 'o' pork lately, that I'm now afeard to look 'a pig in the face.'

"All these little things amuse me; they excite and occupy my mind, and keep away the blue devils of London. Write to me soon, and let the letter be long, and put in it

every information about what is going on in the profession, and believe me,

"Yours, very faithfully,

"H. H.

"Leicestershire, Oct., 1835."

"P.S. Let me have a copy of WARDROP'S book on Blood-letting, whenever it appears. I do not expect him to send one, not having given him a copy of my Orations, which I learn, by a side-wind, he was annoyed at. Let me also have a copy interleaved, for notes and observations of my own, as there is no subject in which I have ever been more interested than that of *bleeding* my patients."

CHRIST'S HOSPITAL.

To the Editor of THE LANCET.

LETTER FROM THE CHAIRMAN OF THE LATE COMMITTEE OF INQUIRY.

SIR,—You have taken a highly commendable interest in the affairs of *Christ's Hospital*, and have, as usual, been successful in aiding the correction of some of the gross abuses which prevail there. I thank you sincerely, in behalf of the children and their *natural* relations and parents for your exertions; and I call on you again to exercise your powerful pen, in reminding their parents' deputed and solemnly-charged guardians, to look first to their charge, and secondly to the manner in which they have acted under it. I have visited the charitable institutions of France, Spain, Germany, Switzerland, and Italy, and the information I there obtained has been improved by subsequent inquiries into our charities at home, firmly impressing me with the conviction that an impartial examination into the management of *Christ's Hospital* must be productive of prospective and immediate good, of the most extensive kind, to the objects of the founder, at once at Hertford and in London.

The medical question, which has so many times occupied your attention, has, at length, been disposed of, in a manner which does not, at the present moment, admit of being re-discussed; and I am sorry to say, that other matters, as regards the health and education of the children, seem to be relapsing into their former state. The unnatural practice of shearing the boys' heads has been revived, and the ringworm still lives and flourishes.

The Committee of Almoners appear to think that they are for ever to exercise their injurious influence over the health and future characters of the children. The expectation, however, is, I fully believe, a vain one. They will no longer find it available, independent, but care

by of "Pray support your committee"! Careless governors, I am sorry to say, do support that committee still, and will continue to do so. The ledgers of the hospital will not be looked at with so much anxiety by them as their own. Still if they would but once, *only once*, take the trouble to inquire, they would, perchance, find that besides the income derived from the interest and possession of Treasurer's balances, and the expenses of residence (the Treasurer's especial perquisites), the salaries of clerks and servants amount in one year to more than one fourth of the gross income of the hospital! Would any of the numerous mercantile governors think that such a sum as 10,000*l.* could be properly, or with safety to themselves, given, in the mere shape of salaries, to clerks and domestic servants, in their own establishment, out of an income of 40,000*l.* a year? The fact I have stated should at least lead them, by analogy, to suspect that their unbounded confidence in the Committee may have been misplaced. Why, sir, the Committee of Almoners of *Christ's Hospital* have never, singly, turn by turn, or as diligent superintendents, gone through the wards and efficiently investigated the conduct of the nurses and other servants. And these gentlemen, too, are auditors of their own accounts. Meetings of Committees of Almoners are held, and that is all, and eight hundred children are committed to the care of servants!

With this brief summary of facts I beg to direct your attention to the circumstance, that a member of the Court of Governors has given notice that on Friday next he will bring under notice my petition, as that of a Governor of the Institution, to the House of Commons, on the subject of the abuses in *Christ's Hospital*. What that Governor expects to accomplish on the occasion, I know not. He may desire to intimidate, but he will not succeed in his object; or he may find vent for feeling of anger at the exposures made in that petition; but be his object what it may, it is my intention to meet the case he may present, only with the petition to the House of Commons, replying no further than by the contents of that document. The petition, you may remember, was presented by yourself from me, as Chairman of a Committee of Governors appointed to inquire into the due and efficient discharge of the duties of certain officers of the establishment, and praying that Parliament would inquire into the truth of the allegations urged therein; and lest the honourable Governor who is to bring forward the motion in question, should have come unprovided with a copy of the petition, I beg, through the medium of your pages, to hand him one. I shall not think it a mark of disrespect or personal attack, if the governor, however he may feel, is in opinion, and I am sure, the same from others.

This noble institution, with its ample funds, would afford, under different and better management, a far more extended sphere of usefulness than it does. The conviction of this has prompted me hitherto in all I have said and done, and it will continue to do so until a correct system of management is adopted within its walls. With my brother Governors I desire not war, but peace, in the distribution of the bounty of the benevolent founder, and in the councils of the Almoners; but where 400 gentlemen, with a charge so solemn as that to which they subscribe, consign their duties to the small body who meet under the designation of a (neglectful) "Committee," then it appears to me that peace on my part, or on the part of any of the Governors, is neither honest to the memory of the founder, nor to society at large. I am, Sir,

Very obediently yours,
WILLIAM BRACKSTONE TARBUTT,
Governor of *Christ's Hospital*.
London, Nov. 25, 1835.

CHIMNEY-SWEEPER'S CANCER.

To the Editor of THE LANCET.

SIR,—You will oblige me by correcting an error into which your reporter has fallen, in publishing some observations which I made at the *Medical Society of London*, last week upon a case of Chimney-Sweeper's Cancer. I did not say that "the exostosis on the tibia of the patient well illustrated the proposition laid down by Mr. Abernethy." On the contrary I thought that circumstance accidental (probably congenital), and having no connection with the cancer on the scrotum, which I believe to be a local disease, brought on by the application of an irritant (soot) to that particular part. What I did say was, that I thought this case illustrated the observation of Mr. Abernethy (that cancer will invade every structure of the body), as it began in the skin of the scrotum, extended thence to the cellular tissue and glands of the groin, to the muscles, the periosteum, and even to the bone, the left pubic bone, which came in contact with the disease, being nearly destroyed.

But, Sir, my question to the Society is of some importance in the treatment of this disease, and with your permission I will now repeat it, to be answered by any of your correspondents; it is this:—Is Chimney-Sweeper's Cancer a constitutional or a local disease? The case which I related would seem to favour the latter opinion, as no disease was found in any other organ of the body. I am, Sir, your obedient servant,

R. L. HOOPER.
London Road, Southwark,
24th November, 1835.

DELIRIUM WITH TREMBLING.

To the Editor of THE LANCET.

SIR,—I was rather surprised at seeing a letter from Dr. Copland on Delirium cum Tremore in THE LANCET of last week, in which he claims the merit of having been "the first who distinguished two species of the disease;" and I was still more surprised at Dr. Copland saying, I am sure inadvertently, "I cannot find that I have made any reference to Dr. Elliotson's lecture on the subject." If Dr. Copland will again peruse the article in his Dictionary, he will find that he *has* referred, among his authorities, to Dr. Elliotson's very lecture mentioned in your foot-note. In the same lecture, and also in a clinical lecture published in THE LANCET for Nov. 13, 1830, a still earlier period, it will be seen that Dr. Elliotson not only had distinguished two great varieties of the disease, the one (the more frequent) not inflammatory, but requiring "to be treated with opium in full and repeated doses, backed by good nourishment, and sometimes to be combined with stimulants;" the other decidedly inflammatory, and not to be cured without "bleeding and starvation," in fact, "requiring to be treated as you would treat phrenitis;" but he mentions also a third variety, "where it is perfectly right to employ moderate antiphlogistic treatment, and to give opium also." Nay, Dr. Elliotson invariably pointed out all these varieties of the disease, and also the incorrectness of the name *delirium tremens*, which he said ought to be changed to *delirium cum tremore*, from the time he commenced lecturing at St. Thomas's Hospital, in 1825; and he was in the habit of mentioning a case, in illustration of the inflammatory type, which he saw many years before that time, in the person of a young county member, whose acquaintance he had made at Cambridge. Of course, I do not mean to imply that Dr. Copland did not also observe the varieties, because I know him to be a most honourable man; but it is evident that he was not the *first* to distinguish them, any more than the *first* to suggest the alteration of the name.

I enclose my name and address, and beg to subscribe myself.

AN OLD PUPIL OF ST. THOMAS'S.
London, Nov. 23, 1835.

It appears to us to be better to retain the term "*delirium tremens*," in the present state of medical nomenclature; first, because it is already in use; secondly, because it is more euphonious than the triple-worded term; and, thirdly, because it is quite in accordance with the general analogy of doctrinal language. *Delirium* is the result of a morbid condition of part of the human economy, and the adjective *tremens* is ap-

pendent (the whole really making but one distinctive word, with a *hyphen* in the centre to denote a modification of that condition). The two learned teachers may be justified according to their own views of the disease in each adopting that particular phrase (Latin or English) which best expresses their notion of the actual condition of the patient affected; but to say, as we presume they would, in advocating a change of terms that *delirium* does not tremble, is to detect a meaning in the old term which (according to circumstances) it scarcely even suggests. As well might we say of *inflammatory fever* or *neurotic palpitation*, that those terms must be abolished, — the latter, for instance, because the *palpitation* is not nervous, — in order to say "*palpitation with nervousness*," "*fever with inflammation*." We could cite a dozen such instances, but by thus changing terms we should convert them from names into sentences, which is not the thing desired.

INQUEST AT FARNHAM.

LETTER FROM MR. G. BURY.

To the Editor of THE LANCET.

SIR,—I appeal to "your own sense of justice and propriety," so loudly proclaimed in one of your editorial articles of Saturday November 14, to insert in an early number of your journal the paper sent herewith which has been called forth by the extraordinary mis-statements to use the mildest term contained in a letter to you from this town, purporting to bear an account of an inquest lately held here, dated October 26th and printed on the above day. In the accompanying document I think you will find most complete contradictions of all the so-called "facts" furnished to you by your correspondent, relating to me; and as, in my opinion, no man who considers himself respectable, or would wish to be thought so could condescend to reply to the author of such "facts" in any other mode than that adopted by me, or to notice any of his statements touching other points of the case, I shall crave your permission to pass on to the remarks made by you, or more fairly speaking, by the writer of the leading article alluded to.

I take the liberty of addressing you, Sir, as being the editor of a public journal, and as having offered observations therein on a case in which I have been concerned, both as medical attendant and witness, rather than from the estimate I entertain of my own sense of justice and of the necessity of this "sense" of justice in submitting such a paper to the public.

spondent into your columns, in which a medical jurist is said to have delivered evidence of the remarkable nature therein specified, without having made prior inquiry as to its correctness, either of the witness in question, or some other party. You may object that you have been misled by your correspondent, in whom you placed confidence, and whom you believed to be trustworthy. Be it so. But were you sufficiently acquainted with his character to warrant your accepting any statements he might choose to transmit to you? Or were you sufficiently acquainted with the relative station, in society and character, of your correspondent and the other medical men here, if, indeed, your new advocate for the necessity of medical coronerships can be called a resident practitioner, to justify you in publishing the like observations from one against the other? I know you were not. You could not have had such knowledge. Therefore, may I not well ask, where are your "justice and propriety," "in publishing the letter to be found at page 256?"

With respect to your "stating that Mr. Portello does not appear to have incurred the slightest degree of culpability," and "there is not a tittle of evidence in proof that the child was poisoned," will you permit me to ask you, on what are *formed* the opinions thus freely given? I have always understood, in my own simple judgment, that it is requisite and essential to be enabled to form an opinion before one can be given. But you hesitate not in pronouncing yours without even having seen the evidence, or having been present at the inquest, — an opinion that can be grounded only on the contents of the letter of your correspondent, from which *per se* (even if it were correct), every person competent to judge must admit your conclusions have been drawn too hastily, and from insufficient data. Your authority with regard to what was found in the stomach, as to how long it might have been in that organ, and how far it operated in being the cause of death, is, questionless, of great value; but, for my own part, I consider that of Dr. Christison at least *equal* as a toxicologist, and if you will take the trouble to refer to the last edition of his excellent Treatise on Poisons, you will discover in pages 799 and 801, matter quite at variance with what you have ventured to assert so "certainly" and "assuredly."

Again, if "Mr. Portello is entirely exonerated from blame," as you have avowed him to be, how can it be "an act of malicious cruelty to make him the object of suspicion or reproach?" Or how is it possible that he should be "an object of suspicion?" In your paper, by whom Mr. Portello was accused or reproached, was any one of the jury said to him, and

I defy you to bring proof of, or even to show malice or cruelty towards him emanating from any quarter. I remain, Sir,

Your obedient servant,
Farnham, Nov. 23, 1835. G. BURY.

[Extract from the Printed Document alluded to in the first paragraph of the above Letter.]

So soon as I read what alluded to me therein (in THE LANCET of Nov. 14th), I wrote to Mr. Woods, the Coroner, requesting answers to certain questions, if it were not incompatible with his official situation to reply to them. His absence from home prevented my receiving the following letter at an earlier date, together with a copy of my deposition taken at the inquisition over which he presided:—

"Friday Evening.

"My dear Sir,—Having seen the garbled case in THE LANCET, I most readily furnish you with a copy of your deposition for your own private information, assured that you will not give it publication. To save time, my youngest son is the bearer of it. I should have felt myself equally bound to have given Mr. Portello a copy of his own deposition upon the same understanding. This was not inquired for. To say nothing of that part of the publication which is grossly untrue, viz. that I had stated a fact to Mr. Rogers of your having administered powder to the child, from whom alone I received this information, the whole of the statement is calculated to mislead the public. He told me he gleaned the circumstance from the parents of the child. As your evidence is now before you, you will think it superfluous for me to answer the specific questions you have put. The verdict certainly was not wholly founded on your evidence, but as connected with other depositions, I have no doubt it made a powerful impression.

"Yours very truly,

"HENRY WOODS.

"To George Bury, Esq."

Having received authority from the son of Mr. Woods, to submit the copy of my deposition, which I am not at liberty to publish generally, to the inspection of two or three respectable inhabitants, I have done so, and, in conformity with the recommendation of a disinterested person, placed it before the two gentlemen, whose names are appended to the document which follows, the former of whom was selected as being one of the clergymen of the place:—

"We have carefully perused the whole of Mr. Bury's evidence given before the coroner and jury at the late inquest, held on the body of the child Catherine Robinson, and can confidently state—*First*,—that Mr. Bury did not use Mr. Portello's name in his evidence. *Secondly*,—That he did not swear that nuxvomica caused the death of the child. *Thirdly*,—That his evidence proves that the child could not swallow at the time he saw her.

"R. SANARY.

JAS. STEVENS.

"Farnham, 21st November, 1835."

(The following are subjoined as the replies of Mr. Bury to the various statements of Mr. Rogers.—En. L.)

Declaration of Mr. Arthur William Woods.

"I hereby declare that I was present at the inquest at Farnham, held on the 17th of October last, and that I heard my father, the Coroner, ask Mr. Bury several times during the examination, whether he could swear that nuxvomica was the cause of the

death of the child, and Mr. Bury as often replied that he could not swear to it, or in other words that he could not pronounce such an opinion.

"ANNA W. WOODS.

"Nov. 21st, 1835."

No charge was delivered. The Jury requested the Coroner to withdraw before all the witnesses in attendance were examined, and in a few minutes returned their verdict, agreed on unanimously.

"The verdict certainly was not wholly founded on your evidence, but as connected with other depositions, I have no doubt it made a powerful impression."—*Mr. Woods's Letter.*

"To say nothing of that part of the publication, which is so grossly untrue, viz. that I had stated a fact to Mr. Rogers of your having administered powder to the child."—*Ibid.*

The truth is, that I sent medicines to be given, if the child should alter for the better in the course of the night, from the effects of a blister which I applied. I told the Coroner and Jury I considered the recovery of the child hopeless, from the first moment I saw her, and when about to communicate what remedies were used, I was stopped by the Coroner, who remarked, "You did all you thought proper to be done," to which I assented, and he then proceeded with other parts of my evidence.

Declaration of Mr. Hewitt, Guardian of the Parish.

"I hereby affirm that I accompanied Mr. Bury at each of his visits to Mr. Portello's shop, previously to the inquest on Catherine Robison, and that on neither occasion was he shown by Mr. Portello, or any other person, a bottle containing jalap in powder, or the situation of such bottle, or any such preparation, in the shop; and I also affirm that that substance was not even named to Mr. Bury.

"JOHN HEWITT, Guardian.

"Nov. 18, 1835."

Declaration of Michael and Ann Robison, the Parents of the Child.

"We declare that we never stated to any one, or at any time, 'that the child became sick, very sick, from the medicine given by Mr. Bury, and that it was much convulsed after taking it.'—We do also hereby attest that the child had no vomiting, after Mr. Bury first saw her.

"MICHAEL ROBISON.

"Witness,

FREDERICK TRIMMER,
Assistant Overseer.

"Farnham, 18th November, 1835."

An idea exists in the minds of some of the inhabitants of this town, that my evidence before the coroner and jury was intended to criminate Mr. Portello, and I believe he himself has imputed the design of doing so to me. To those who know me, I trust it is quite unnecessary to disclaim having had any such motive; but if others entertain doubts upon the point, the following brief statement must remove them from every candid mind.

It was well known (and made known to Mr. Portello also from my own lips) to the parish officers, to the coroner, and several others, that my suspicions of guilt, up to the hour of the inquest, fell upon another party, whom I will not name, since such suspicions have subsequently proved groundless. His name, as above attested by the Rev. R. Sankey, and James Stevens, Esq. was not mentioned to me, but the *individual* evidence touching him, came from other testimony than mine. The circumstance I am now going to relate, will indeed show that I really had friendly feelings towards him. Late in the evening before the day of the inquest, Mr. P. requested me to walk with him to the house where the child was lying, a distance of nearly a mile, and said he would feel much obliged by my accompanying him, for he had some questions to put to the parents which no other person than a medical man could appreciate. I readily and instantly complied with his request. Mr. D'Esterre, my brother-in-law Mr. Hewitt, and Newell, the high constable, who were in his shop at the time he asked the favour of me, went with us. I confess I heard him put no other question to the parents of the child than this, "Why did you not send for Mr. Bury sooner?"

In conclusion, I here repeat that my *sole* motive in publishing these observations and contradictions, is to vindicate myself from the charges involved in the foregoing misstatements.

G. BURY.

Farnham, 21st November, 1835.

COURSE OF LECTURES ON DISEASES OF THE BRAIN AND NERVOUS SYSTEM, BY M. ANDRAL.

In the next Number of THE LANCET will be published the first of a series of Lectures now in the course of delivery at Paris, by the celebrated M. ANDRAL, on the Diseases of the Brain and Nervous System, reported expressly for insertion in THE LANCET, and published with the express permission and approbation of that renowned pathologist. We content ourselves by merely making this announcement, as the importance of the subjects to be treated in the lectures, and the celebrity of the lecturer (who has devoted an immense portion of time exclusively to the study of the subjects by which they will be illustrated), recommend them to the notice of the profession without a word of comment on our part.

THE LANCET.

Vol. I.]

LONDON, SATURDAY, DECEMBER 5, 1835.

[1835-36.

LECTURES

ON

DISEASES OF THE BRAIN AND NERVOUS SYSTEM,

NOW IN THE COURSE OF DELIVERY IN THE UNIVERSITY OF PARIS.

By M. ANDRAL,

Physician in Chief to the Hôpital de la Pitié, and Professor, and Lecturer on the Principles and Practice of Médecine, in the Faculté de Médecine of Paris.

LECTURE I.

PRINCIPLES OF INVESTIGATION.

GENTLEMEN,—In the course which I am about to deliver this session, I propose to draw your attention specifically to diseases of the brain and its appendages; in a word, to affections of what is called "the nervous system,"—those diseases which affect the organs of relation, commencing with the nervous system as the chief agent by which the various acts or functions of relation are produced and regulated.

Before we enter immediately upon the study of this most interesting class of diseases, permit me to present to you a few preliminary considerations on the difficulties by which the physician is surrounded in his pursuit of knowledge in this particular branch of medicine. The study of diseases of the nervous system is peculiarly difficult, not only on account of the obstacles which impede the advancement of medicine in general, but from various circumstances connected more intimately with the system itself. In the first place, we desire to collect materials for the ground-work of any general views upon this subject, we find ourselves compelled to examine a vast variety of works, and to spend an immense portion of time in the collection of facts, which are scattered through a great number of authors, written at different times, and published

A great deal has been known in latter years, and the knowledge of the system, and its

thological anatomy; but I know of no single work which may be said to afford any thing like a complete view of the question, which embraces all the facts that bear upon it, and at the same time does not leave untouched a great number of the most important and interesting points on which correct principles are to be founded. But the subject, difficult and arduous as it is, from its own nature, is rendered still more difficult from the various opinions and theories which prevail amongst the best physicians on almost every single question connected with the physiology and pathology of the brain and nervous system. It is not now the time to touch upon the disputes to which these have given birth, but you will have occasion to observe, during the present course, how very difficult it is to arrive at any thing like the truth, or even to obtain a fixed idea on any point, amidst the multitude of conflicting opinions, and the host of contradictory facts, which we shall find stated and vouched for upon the most respectable authorities. Yet all these we must examine and discuss, with the hope of obtaining some determinate principles, carefully sifting opinions, and weighing and comparing the facts on which they have been founded. I do not mean to affirm that medicine, as a science, is exact or complete. No; I certainly would not venture to assert *that*. There are many points in the science upon which we are as yet by no means sure; but uncertain as our knowledge may be with regard to the causes and nature of several diseases, it is infinitely less sure, far less firmly based upon rational grounds, or supported by positive *data*, when the diseases of the nervous system become the object of our inquiry. In the study of any disease, or in the investigation of the diseases of any particular part of the body, or any system, there are three or four circumstances to which the attention of the physician is almost exclusively directed, and which he always endeavours to determine, though he may not expect that his efforts will always be crowned with success. His *first* object is to ascertain the causes which have determined the disease: his *second* is to observe the external or internal symptoms which reveal its existence: his *third* is to study the pathological phenomena or lesions

which the disease produces in the different tissues; and, *finally*, by carefully meditating on the causes, the symptoms, and the pathology of the disease, he endeavours to fix upon a rational treatment. This is the manner in which we should proceed, were we to investigate diseases of the chest, of the abdomen, or of the circulating or any other system; but in diseases of the nervous system, we unfortunately find that the study of the causes, the symptoms, and the treatment, is surrounded with difficulties of a peculiar nature, which we do not find in any other class of disease. We shall now lay before you an account in detail of some of those difficulties,—not with a view to discourage you in the pursuit of professional knowledge, but in order to render your progress more easy, by pointing out at once some of the principal obstacles with which you will have to grapple, and prepare you to surmount or remove them.

If we begin by investigating the causes which determine the symptoms of other diseases, we have to consider *first*, the action of external agents; *secondly*, the reaction occasioned by the operation of several of those agents; and *thirdly*, the process or influence which is called "sympathy."—a trouble produced in the functions, and often in the structure, of one part of the body, or of the economy in general, by derangement in the function or structure of another part.

Applying this division to the nervous system, we find that the latter is not influenced by the external world, or at least, is but little subjected to those changes which external agents incessantly tend to produce in other symptoms. The respiratory apparatus is constantly and of necessity exposed to the action of the atmospheric air, and to the various impressions, of a thousand sorts, which are apt to be conveyed through that medium. The intestinal canal is also daily exposed to the action of the various alimentary and other substances which are applied to its surfaces. But the central nervous system is, by a peculiar provision, withdrawn from the influence of most agents of this kind. It is, however, subject, in the the highest degree, to effects of the third species of causes to which we have alluded. Indeed, an attentive observer of the phenomena which take place during disease, must be convinced that we can have no organ slightly deranged, no function troubled, even in an insignificant manner, without a corresponding change being produced in the nervous system. No matter whether the primary change takes place in a fluid or in a solid of the body, in an organ essential to existence, or in an apparatus of secondary importance. The central nervous system, or that force which presides over life, partakes more or less of the disturbance. Its ordinary phenomena are then no longer manifested, and the economy evinces symptoms

of general trouble. Hence, in all diseases, the nervous system is affected in a variety of ways; and hence, also, arises one great difficulty in pursuing the study of those diseases which are peculiar to it. Take, for example, any disease, examine its symptoms, separate those which depend immediately upon the organic change from those connected with a lesion of innervation,—select a number of diseases indiscriminately, and see how many of the most important among them frequently depend upon the latter. In gastritis, in hepatitis, in inflammation of the lungs or the abdominal viscera, how many symptoms have we which can be referred to the mere inflammation of the part,—to the simple physiological change which occurs in the condition of its vessels? Examine the symptoms with care, and you will find that the greater part of them depend upon the trouble occasioned by the local disease, in altering or perverting the vital force,—that they are, in a word, secondary affections of the nervous system, which commands and directs all the other systems of the economy,—which stamps its peculiar physiognomy on the primary disease, determines its character and gravity, regulates its march, produces its complications, and, finally, directs the therapeutic indications which we are to follow. In almost all the other organs of the body, we can find the cause of the malady in the structure of the organ. Pathological anatomy, cultivated as it has latterly been with arduous and perseverance, has laid open to us the changes which take place in the organic structure of the different apparatuses during the course of most diseases by which they are affected; but in the nervous system pathology furnishes little or no aid of this kind, and we are compelled to look for a number of causes of its diseases which are totally unconnected with physical modifications. Hence arises a principal difficulty in the study of nervous diseases of the system, which assume a variety of characters and types, under the influences of causes which, having no sensible effect that is appreciable to the senses, often escape our observation, or involve us in an obscurity which it is too often impossible to dissipate. Though our knowledge of nervous diseases may still be very imperfect, we are sufficiently advanced to affirm that they vary considerably, according to the different stages and periods of life; that they are modified by climate, and even by atmospheric changes; that the tendency to several nervous affections is augmented or influenced by the education and profession of the individual, and by numerous other moral agents, as must be familiar to every physician who has practised medicine successively in the country and in the populous capitals, like Paris. According to the form of the disease, religious persuasion

stage, according to the degree of civilization, and the more or less extensive partition of enjoyments which operate with immediate influence on the moral man, we find that diseases of the nervous system become at one time intense, at another feeble, are confined to particular classes, or are diffused through vast masses of the population. Diseases which at one time were obstinate of treatment and frequent in recurrence, become at another time mild and rare. Affections with which we are now familiar, were seldom observed in earlier and more simple ages; while many nervous diseases have altogether disappeared and become extinct, from the different relations of man in civilized life.

This uncertainty in the form and character of disease, more peculiar to nervous disorders than to any others, from some of the causes we have just pointed out, must render it difficult to appreciate a great number of circumstances connected with them; but this is not all: even when we would determine the existence of any nervous disease, seek its place in the nosological scale, in a word, give a name and seat to the disorder before our eyes, we find ourselves surrounded by a number of peculiar difficulties which frequently frustrate our best-directed and most assiduous efforts. Some, perhaps the principal, of these obstacles, gentlemen, arise from the absolute insufficiency of our means of investigating diseases of the brain and nervous system. Disease of an organ is betrayed by a change in its physiological functions. The change of structure or of physical conditions in many of the chief organic apparatuses, makes itself known to our senses, and hence arises the admirable precision of diagnosis at which we have latterly been enabled to arrive in diseases of the chest and abdomen. By the aid of auscultation and percussion, or, in other words, by bringing our senses to bear immediately upon the injured part, we can fix with wonderful accuracy, not only the seat, but even the precise nature, of various disorders which occur in those two great cavities; but the peculiar nature of the functions of the brain and nervous system, the difficulty hitherto experienced of establishing any connection between the function of the organ and its structure, the absolute impossibility of applying our senses with any advantage to an appreciation of the normal or abnormal physiological conditions,—these and several other causes compel us, in diseases of the nervous system, to abandon the aid of our senses, and have recourse to simple induction. But this latter guide is uncertain: it furnishes to different investigators, an immense difference of results, and thus the study of nervous diseases, difficult as they are, and the more so, as their nature, becomes still more obscure from the insufficiency of our means.

A second obstacle which presents itself to us in our examination of diseases of the brain and nerves, arises from the absurd manner in which theory has been mixed up with observation. The number of facts collected is considerable, but their value has been much diminished, and their appreciation often rendered obscure, if not impracticable, from the unhappy tendency which too many writers have, to build up suppositions without any foundation, which they bring forward at every instant, and to which the true facts are frequently compelled to yield, or they are distorted into an apparent reconciliation. Thus for many years the study of diseases in general, and of the nervous system more particularly, has been retarded by a wish to explain all that we witness in the course of disease, by ascribing it to an augmentation or a diminution of normal excitement. No doubt in many disorders which have an hyperdynamie, or an adynamie, we find the vital force elevated beyond the normal type, or depressed below its natural standard; but in a great number of diseases we have a third state, which we cannot neglect without falling into numerous errors; we have something more than a *plus* or a *minus*: we have a condition that cannot be referred to exaltation or diminution of the vital force; we have a change of quality in that force, an aberration, a perversion or deprivation whose influence is perceptible in almost every affection, and whose existence we cannot neglect without exposing ourselves to all the errors of the Brunonian doctrine. The existence of this state of ataxia in various disorders may be directly proved, in others it may be inferred from analogy; thus in delirium, in several forms of convulsions, &c., we have evidently an aberration or a deprivation of the vital force; not an exaltation of it, or an excitement. When delirium exists in the course of fever, or of inflammation of the brain, I say there is an aberration of the intellect, a deprivation of the vital force in that part of the economy, and I can prove this from the very nature of the disordered function, but I cannot admit that there is an excitement, or an elevation of a normal condition.

Another cause of the difficulties with which we meet in studying diseases of the nervous system, arises from the circumstance that various organic changes in the brain, a great diversity of lesions, may give rise to nearly identical symptoms, and in the actual state of the science we are compelled to use the utmost reserve whenever we would attempt to explain, by the nature of the lesions found in the dead body, the functional derangements presented during life by the brain or its appendages.

You need not go deeply into the history of cerebral disease to be convinced of this truth. Let us take, for example, two individuals who are labouring under

examination of the dead body cannot explain the various phenomena we observe during diseases of the nervous system; and if we place too exclusive a reliance upon pathological researches, we shall become involved in contradictions, from which escape is very difficult.

If we look for the cause of this slow advancement of the science in diseases of the brain, we may perhaps find it in the circumstance that a great number of functional disorders may really exist without any change of structure sufficiently pronounced to be observed by our senses after death. This, I say, may possibly be the case; the lesion of innervation may be sufficient alone to produce various troubles in the economy, without being accompanied by any organic derangement of tissue; however, we should be inclined to suppose the contrary from analogy. These lesions very probably do exist, although they have hitherto escaped all our researches. We have, therefore, the greater need to increase our diligence, multiply our observations, and examine with most minute attention the slightest change not only in the arrangement and texture of the nervous system, but also in its composition, and at the end we shall perhaps arrive at truths whose discovery is now almost unlooked-for.

We are indebted, as I said before, highly indebted, to pathological anatomy for some of the most important discoveries in medicine which have been made in modern times; but it is unfortunately an effect of the ardour with which one branch of the science is pursued, that many other considerations, of minor importance indeed, but still necessary to the full knowledge of disease, have been comparatively neglected. Thus, perhaps, we have not paid sufficient attention to the relative development of the several parts which, taken together, constitute the *ensemble* of the nervous system. Almost exclusively devoted to the research of changes in the texture of organs, we have neglected to inquire in what manner an irregular development of certain portions of the brain may be a cause of trouble to the functional actions of the whole organ. We have many reasons for believing that loss of equilibrium in the normal growth of the different portions of the cerebral mass, may become the cause of deranged equilibrium of its functions, just as well as if the change were operated in the structure of the part. I merely throw out this idea as a matter for your reflection; the time for discussing the question has not yet come. Again, there are certain changes of nutrition, certain phenomena connected with the chemical composition of the brain, which may not be without influence on its functional manifestations, and therefore deserve our attention while examining the history of disease in an organ where it is so diffi-

cult to trace after death the physical change that may have been the cause of accompaniment of the original malady. In later times, gentlemen, it has been proved that the elements which compose the brain vary from one period of life to another. Thus in the infant and child the quantity of aqueous matter predominates over the albuminous and the brain itself presents an augmentation of volume from birth up to the age of puberty. In the adult, again, the quantity of phosphorus which enters as a component into the chemical composition of the brain, is greater than in the child or in the old person. The quantity of phosphoric matter, inconsiderable in the child, acquires its maximum in the adult, and again diminishes in old age. During the latter period of life the brain shows evident signs of diminished nutrition; its several diameters are reduced by some lines, and its specific gravity is from one-twentieth to one-fiftieth less than in the adult.

These are questions which as yet have only been touched upon as connected with diseases of the brain, but they deserve our serious attention. In the absence of anatomical lesions, it is not altogether irrational to conclude, that perhaps some diseases of the nervous system may be explained by chemical changes in the substance and complication of the brain; but this only proves that at a future time we may be in a condition to give a satisfactory reason for several phenomena which are now involved in total obscurity. The ideas which I have just thrown out upon this point, are mere suppositions, that may be confirmed or overthrown by subsequent observations; it is a such that I would wish you to receive them and not as facts that obtain the value of demonstrations.

Let us now turn to another part of the subject, and consider, briefly, diseases of the nervous system in a therapeutic point of view. Here also you will find yourative beset by many unexpected difficulties. In various abnormal conditions of the nervous system, the patient shows marks of excitement, the energy of the nervous force appears elevated, and the symptoms seem to indicate such means as usually operate in diminution of the vital power; but in these cases, if you employ blood-letting to any extent, instead of allaying the nervous trouble you aggravate it, and the indications of treatment upon which you had reliance in disorders of the other systems, here leave you in fault. This is particularly seen in many of that class of diseases called "neuroses," where sanguineous emissions always exasperate the symptoms of exaltation which seemed to indicate them, and where we are compelled to have recourse to quite a composite system of treatment. In some of these intense inflammations of the brain, where the only hope

besides the copious and repeated bleeding, this latter measure is attended with decidedly injurious effects; the excitement, instead of being calmed by the loss of blood, rapidly increases, and is soon followed by a fatal exhaustion of the vital power.

In many other diseases, also, some peculiar nervous state exists, which will not admit of blood-letting. In chlorosis, for example, we have signs of a nervous exaltation; but these are dissipated under the use of quinine, of cold effusions, of strengthening diet, exercise, &c., which bring back the harmony between the functions of the several parts of the nervous system, while sanguineous emissions would, on the contrary, only tend to keep up the disorder. Another difficulty in the appreciation of the effects of remedial agents in disorders of the nervous system, is the immense and varied power enjoyed by the imagination over almost all our functions; the force of a vivid imagination, the power of energetic belief, the influence of religious or superstitious impressions, are capable of producing and curing diseases, not only such as depend upon derangements of the nervous system, but others which have taken much more profound root in the economy. Of this, history affords us proof every day, without ascending to a period of remote antiquity, or the miracles of the royal touch. How easily can we explain by the imagination, many of the cures obtained from the magnetisms of MESMER, down to the infinitisms of homeopathy! It is the influence of this same imagination which constitutes the force of the charlatan, working a cure by invisible means, which is attributed to the nullities he administers: in a word, the influence of the imagination on the normal and abnormal conditions of the human body, forms one of the most curious parts of the history of man.

There are, perhaps, few professions which require a greater combination of varied and extensive knowledge, than that of the physician; and if this be true for the study of disease in general, we feel a still greater necessity, when entering on the investigation of nervous diseases, of preparing and clearing our way by a previous study of the other accessory sciences. Above all things, gentlemen, your efforts should be directed to the acquisition of anatomical knowledge; not of the rough imperfect anatomy with which you are contented in the commencement of your education, but of minute and delicate anatomy, which alone can enable us to throw any light on the changes of organization that take place in the brain and nerves. You will find this minute research the most precious aid in your investigations, and it is the only method by which we can arrive at an interpretation of the phenomena already present, without any further explanation of

them in the actual state of the sciences. Cultivate then, I say again, minute anatomy, and believe me that if you would pretend to advance this obscure portion of medicine, you must, above all things, be a profound anatomist.

The knowledge to be derived from comparative anatomy and from experimental physiology is also not to be neglected. In some cases you will observe the movements of the lower extremities extensively lost, though the lesion in the spinal marrow is comparatively insignificant; in other cases the loss of motion and sensation is less perfect, although the injury of the spinal marrow may be carried to such an extent as to cause its complete separation into two portions: it is difficult to understand how this can take place, but without attempting altogether to explain it, I may observe, that in some fishes I have seen the nerves completely separated from the spinal marrow, and yet sensation and motion have been conveyed from it to the distant parts of the body, through a fluid.

We can also derive considerable assistance towards the clearing up of certain obscure points in pathology, from physiological experiments; thus we have been able to understand and explain a great number of interesting points connected with paralysis of the face, only since the period that experiments have demonstrated the different functions attached to the fifth and seventh nerves. Again, consider the great light which experimental physiology has thrown on the pathology of the spinal marrow; in man we have frequent examples of an injury affecting only the anterior columns of the spinal marrow, and the functional derangement is betrayed by a greater or less loss of the motile power; in other cases the lesion is situated chiefly in the posterior columns, and here sensation is the function which suffers. How could we explain this difference without the beautiful discoveries of some modern physiologists, who have shown that the posterior columns of the spinal marrow preside over sensation, while its anterior portion is chiefly destined to regulate sensation!

The difficulty of tracing the morbid phenomena presenting themselves during life, to certain organic lesions, may, in some cases, perhaps, depend upon our not searching for the lesion in the place where it really exists, and this often, in turn, depends upon a neglect of physiology. Thus, in many instances, a patient goes blind without any sensible alteration in the structure of the eye. After death we examine the optic nerves, their commissure, the thalami, in a word every portion of the brain supposed to bear any relation to the sense of vision; and we find all these parts equally free from any appreciable lesion. In another case the sense of hearing is deranged, or altogether lost. We examine the internal ear, the trau-

fect of the *fourth* molis, the stric in the floor of the fourth ventricle, and every thing presents a normal appearance: are we therefore justified in concluding that the loss of sight and hearing in these cases did not depend upon change of structure in the nervous system? I do not think so, gentlemen; we have omitted in our investigations an essential element; experiments have demonstrated that the fifth pair of nerves is an accessory nerve to the functions of the different senses; nay, more, comparative anatomy teaches us that the branches of the fifth pair may themselves become nerves of sensation in certain animals who possess organs of sense that do not exist in man, or in other animals placed low in the scale of creation, this accessory nerve actually becomes a sensitive nerve, and supplies the organs of sight and hearing: hence it is by no means improbable that in many cases of blindness and deafness, the loss of those two functions may depend upon a lesion of the fifth pair of nerves, or some of its branches, and not upon an injury to the principal nerve distributed to the diseased organ.

Thus, gentlemen, you see how closely these different branches of knowledge are connected together; how pathology is aided by comparative anatomy and experimental physiology, and how necessary it is to cultivate these latter branches of the science if we would hope to take a distinguished part in the advancement of the former.

I have thought these considerations upon the various difficulties that present themselves in the study of nervous diseases, of sufficient importance to lay them before you, gentlemen, in some detail. Let us now explain, briefly, the order we propose to follow in the present course. We shall first describe the different lesions of the central nervous system, commencing with the most simple forms, and thence passing to the more complicated; we shall then take up lesions of the nerves; and, finally, terminate with a review of those disorders which are generally attributed to a lesion of the great sympathetic nerve. We have already seen, as regards the other principal systems of the economy, that diseases may be distinguished into *Lesions of Function*, and *Lesions of Structure*. The same principle of division holds good with respect to the brain, and we shall soon have occasion to demonstrate how the influence of this organ extends to all parts of the economy, modifying disease in a peculiar manner, and stamping all with a characteristic mark.

Finally, with regard to the spirit in which we propose to conduct the present course, we may say that its chief object shall be a just appreciation of facts. Some of these facts are premature, and as such cannot be taken into account; others are demonstra-

ble, and upon those principally shall our deductions be founded; others, again, are merely probable, but are by no means to be neglected from that circumstance. We are not of opinion with those who say that a probable fact is no fact at all, "*un fait vraisemblable est un fait non-vrai*." On the contrary, many of these possess a very great value, and instead of turning from them with neglect, we should endeavour to verify and appreciate them. Lastly, some facts are false and inaccurate; but even here I would remark to you that many facts are supposed to be so, merely because they do not agree with our own theories, with the ideas we have been taught to adopt: you must, therefore, weigh each fact with care and impartiality before you decide on its rejection, for nothing is more fatal to the science than that absurd cynicism which believes nothing that it does not see. Our last care, gentlemen, shall be to notice some of the principal theories which prevail with regard to disorders of the nervous system. We cannot pretend to expose all; we shall, therefore, confine our attention to the most plausible. I am not one of those who run after hypotheses and theories, but as a teacher it is my duty to lay them before you, and thus keep pace with the progress of the science, for we have often seen the most interesting and important discoveries, whose authors commenced by inventing hypotheses, and terminated by proving them.

ON THE

NATURE AND QUALITIES OF FLAME.

By W. REID CLANNY, M.D.,

Sunderland.

WHEN a simple body is burnt the flame is uniform throughout; but when compound bodies are burnt, the flame varies considerably, depending upon the nature of the combined gaseous substances inflamed, and producing a variety in the intensity and colour of the light.

As a familiar example, I will commence by giving a correct account of the phenomena of the flame afforded by a candle, and by way of explanation, append a diagram of that flame, afterwards describing the experiments which led me to the conclusion I have adopted, and the apparatus employed.

Surrounding the flame is a thin

Arabic characters (3.2.3), we always find a clear blue flame which chars the wick from the moment it is lighted, and in forming a base for the light-giving flame, at this point, the two flames show a blue-white light at their junction.

Immediately surrounding the top of the wick we find a conical space (2), which forms a centre to the yellow-white flame, and which is less transparent and less luminous than the yellow-white flame, immediately surrounding it.

Round the space (2) we observe the yellow-white or light-giving portion of the flame, which is also conical (3.3.3), as all heated gases are in ascending, by reason of the uniform pressure of the atmosphere.

Surrounding the last-mentioned light-giving atmosphere (4.4) we find an atmosphere which is, generally speaking, invisible to the eye, except we use a large coarse candle in a very dark room. This atmosphere is diaphanous, and surrounds the light-giving flame at every point.

Externally to this invisible flame we find another still (5.5.5), which is composed of nitrogen and carbonic acid gas, but as, of this atmosphere, and of all other parts of the flame, it will be my duty to treat more at large, I will commence by stating, that when we hold a piece of fine brass wire across the flame of any description of candle or oil-lamp, the atmosphere (5.5.5) does not effect any change in its appearance. In the atmosphere (4.4) which, as remarked above, is also invisible, we find that the wire instantly becomes yellow-white, from the great heat afforded by this invisible flame.

Immediately within this invisible flame we find (3.3.3) the light-giving flame, and at this film, or atmosphere, of yellow-white flame, the wire becomes red-hot only. In the centre or the obscure part of the flame of the candle (2), we do not find that the brass wire is so much heated as to give it the tint of what is called "cherry-red." Indeed, I am of opinion that were it not for the conducting power of the wire itself, this obscure portion would not give to it any appreciable augmentation of heat; for, assuredly, this opaque or central portion of the flame, is not in a state of combustion, as I expect to be able, very shortly, to demonstrate. When we place before us a candle of any description which has been burnt for some time, and extinguished in the usual manner, then holding any flame to the wick, we find that the first appear-

ance of ignition is a clear blue flame, which I have discovered by experiments to be carbonic oxide gas. This blue flame, as it continues to burn, will augment in extent, and soon afterwards will show a white flame upon the top. This white flame will gradually augment until it become the light-giving flame of the candle.

The base of blue flame gives out a powerful heat, which not only chars the wick, but also melts the tallow of the candle, and this melted tallow is pumped up, as it were, in the heated interstices of the wick in the manner of fluids in all capillary tubes. At the top of the ignited wick we may readily observe, without the aid of a lens, the inflammable gases springing up into the centre or opaque part of the flame (2), which may be seen more readily after the wick has been snuffed. This liquid or melted tallow, being composed of carbon, hydrogen, and oxygen gases, is manufactured by the heat of the flame, and becomes an empyreumatic oil,—olefant gas, bi-hyduret of carbon, and carbonic oxide gases, suspending a considerable portion of free carbon; and these substances, when in a state of combustion, we call "flame."

Carbonic oxide gas is formed whenever carbon is burnt without its receiving the needful quantity of oxygen gas to cause it to pass into carbonic acid gas. Carbonic oxide gas is remarkably inflammable, and takes fire in the open air when it comes into contact with iron at a cherry-red heat. It is, therefore, in the first instance, burnt at the base of all flames into the composition of the gases of which it enters, as we may observe in the familiar instances of lighted candles, oil-lamps, and gas-lights.

When the free carbon is in excess, in the *tabula flamma*, a portion of it is, during combustion, attracted into the body of the blue or carbonic oxide flame, and there contributes, in a very beautiful manner, to the augmentation of the light at the base of the flame.

When carbonic oxide gas is burnt by itself in the open air, it has, also, its invisible flame, and over this there is an atmosphere containing carbonic acid gas. The invisible flame of carbonic oxide gas has exactly the same properties as the white or light-giving flame when it is burning in a cylinder of wire gauze, except that no water is formed in the combustion, as hydrogen gas is not present.

I now enter upon the subject of inquiry in respect to the nature of the opaque portion of the flame, marked 2 in the diagram.

Into a piece of wire gauze (*vide diagram*) I inserted a brass tube four inches long, and the eighth of an inch in calibor.

It will readily be understood that when I held the piece of wire gauze horizontally, so as to cut off and consequently extinguish the upper half of the flame, the centre or opaque part of inflammable gases not being ignited, would be conducted up the brass tube in the manner of a chimney. When this was neatly and steadily performed for a minute, I could readily ignite these gases as they sprung from the centre of the flame, and I always observed that the flame at the top of the tube was remarkably brilliant. Upon conducting these gases into a tube of glass open at top and bottom, I was enabled to collect a sufficient quantity thereof for experiment, and I found that it consisted of the *pabulum flammæ*, above mentioned,—that generally the olefant gas was in excess, and hence the strength and beauty of the flame. In all instances I found a considerable quantity of free carbon suspended in these gases. I found no oxygen gas in this opaque portion of the flame. Indeed, it could not be expected to be found there, because, as I have stated above, this portion of the flame is not in a state of ignition which would not be the case did it contain oxygen, and because in the combustion in the body of the wick, which converts it into a state of charcoal, all the oxygen contained in the tallow, wax, or oil, is expended in this combustion.

We now come to the yellow-white or light-giving portion of the flame (3. 3. 3). This flame surrounds the opaque or central portion of the flame, except at that part at which it comes into contact with the base of blue flame. This flame, as may now be readily understood, is composed of the substances above-mentioned contained in the centre or opaque portion of the flame. In a word, this is the only true light-giving portion of all flames, and has its dependence upon the invisible atmosphere (4. 4. 4) which surrounds it, and to which I must now advert.

Surrounding the light-giving flame, and the base of blue flame, we always find an invisible flame. This invisible flame will, in some degree, become visible when we cut a black card into the exact form and size of

the light-giving flame, and, in an otherwise dark room, completely eclipse the light giving flame. In such case, though the flame be scarcely visible, we may observe that it is uniform throughout, and is about the eighth of an inch in thickness. This invisible flame is of the greatest importance, for without it we should have no flame whatever.

From numerous experiments with the wire-gauze and brass-tube apparatus, I am satisfied that, at every point, highly heated free carbon is attracted from light-giving flame, and is burnt in the atmospheric air surrounding the flame on all sides, and which air is at all times moving in a current over the flame, from below upward, so that as fast as the atmospheric air affords sufficient oxygen for feeding this invisible flame, it, viz. the heated surrounding atmosphere, is carried upwards, by reason of its expanded state, effected by the intense heat at all times given out by this invisible flame.

This invisible flame instantly fuses fine brass wire, which the white or light-giving portion, in some instances, requires a considerable time to accomplish. I am well assured that this invisible flame is perfect throughout, as I have examined it carefully with powerful lenses; and, also, that by the great heat which it gives out, the inflammable gases of every description are burnt, and that without it, flames of every description could not continue for three seconds.

When we blow upon any flame, with heated air, we drive away this invisible or heat-giving flame, and if we continue to blow, we next drive off the white flame and, lastly, the centre, or magazine of inflammable gases, and thus mechanically extinguish the flame, but not by the current of "cold air," as Davy and others after him supposed. (Of this more hereafter.)

Over the invisible flame we have another atmosphere (5. 5. 5), of which I will now give some account. The smallest engraving represents a glass apparatus exactly of the same size as here represented.

This glass apparatus is composed of two tubes, which project from a bulb, into the latter of which lime-water is poured (by a small funnel), which is represented by the dividing line. I hold the aperture of one of the tubes to any part outside the invisible flame, in such a manner that a small card may pass through the little aperture, and the flame, outwards, taking the

water remain steady in the glass bulb. I allow this current to be established for a few seconds, and then place the fore-finger of the right hand upon the aperture of the outward tube, and the thumb of the same hand upon the aperture of the tube which had been next to the flame. I now very cautiously agitate the lime-water contained in the bulb. In all instances I have uniformly found, that the lime held in solution in the lime-water became visible as a carbonate, by reason of its union with the carbonic-acid gas, conveyed by this glass apparatus from the atmosphere immediately surrounding the invisible flame. This atmosphere of carbonic-acid gas I estimate at one-tenth of an inch in thickness.

As mentioned above, this atmosphere is carried upwards as fast as it is formed, for the reasons there given. Hence the necessity of the constant supply of oxygen gas which our atmosphere affords, and hence the brilliant combustion which takes place when inflammable substances are burnt in oxygen gas.

The invisible flame is destroyed when we hold any incombustible substance against it, and, consequently, the yellow flame recedes at that point, or, rather, is destroyed. Instantly afterwards a new invisible flame is formed, and when we press the incombustible substance forward at that place, the yellow or light-giving flame is again destroyed, and so on until the light be totally extinguished or destroyed. When we arrive at the opaque or centre portion of the flame, we shall find that a considerable portion of free carbon will be precipitated upon the incombustible agent. When we place an extinguisher upon any flame, we will find that it does not come into contact with the flame, even though it be extinguished, because a sufficient portion of oxygen gas is not allowed for the formation of the invisible flame. These phenomena take place with flames of all description into which carbon enters. I need scarcely remark that the purer the atmospheric air, and the greater the portion of carbon which enters into the composition of the above-named gases, the more powerful, *ceteris paribus*, will be the combustion or explosion of these gases.

When we hold a piece of wire-gauze web, of from 28 to 30, both warp and woof (such as Sir H. Davy recommended to be employed in his safety-lamp, to any flame in which carbon is burnt, we shall thereby prevent the formation of the invisible flame within the wire gauze, and another invisible flame will form nearer the centre of the light-giving flame. If we now follow the light-giving flame with the wire-gauze web, we shall find that it will again recede from the wire gauze, and a new invisible flame; and we shall find that the light will be immediately be exting-

guished, or, in other words, the light will be totally destroyed.

When we employ a web of wire gauze, the meshes of which are greater than that mentioned above, we shall find that the flame (no matter of what description it may be) will pass the wire-gauze barrier.

Sir H. Davy, and, after him, many eminent chemists, supposed that the prevention of the passing of flame by the wire gauze which he employed in his safety-lamps, was effected by the "cooling power" of the wire gauze, but this is not the case, as my experiments in this paper testify.

We know, from what I have stated above, that if the invisible flame be prevented from being formed by the above-named agents, so that there may be a deficiency of oxygen gas in Davy's safety-lamp, combustion cannot be continued, and hence the comparative safety afforded by this lamp. But it is needful to assert and maintain that the formation or nonformation of this invisible flame accounts for all the phenomena which that distinguished philosopher referred to the cooling power of the wire gauze.

The more this position is known, and, indeed, I may say, the more that my experiments are tried by competent judges, the greater assurance of their correctness will, I trust, be entertained.

Having visited several very "fiery coal-mines," I am assured that when pitmen are hewing coals they seldom cast an eye to their safety-lamps, and if they did the dense atmosphere of coal-dust would prevent their observing the phenomenon of fire-damp burning in the safety-lamps, as, in fact, there is, in nineteen cases out of twenty, no augmentation of light when fire-damp burns in a Davy-lamp, as I have had reason frequently to remark. Besides, if fire-damp burn several times in a Davy-lamp, the wire gauze becomes oxydated, and, falling in pieces, cannot prevent the flame of fire-damp from passing. Should an accident, such as any pitman's working-tool, unwittingly penetrate the cage of wire gauze in the Davy-lamp, during the prevalence of fire-damp in a coal-mine, the flame of course would pass thereby into the atmosphere of the mine; or should any part of the wire cage be rusted, the fire-damp would soon pass at that part, and, in such cases, explosion of the coal-mine would follow. Another source of danger arises from the following cause:—When the fire-damp is mixed with very pure atmospherical air in the coal-mine, the flame in the Davy-lamp burns so steadily, and with such power, that should the pitman either inadvertently, or through fear, run quickly along the gallery of the mine, we know that the flame of fire-damp would in such case pass out from the wire-gauze cage of the Davy-lamp. It will not appear presumptuous in me to assert that my newly-invented apparatus, being exceed-

ingly simple and easily to be understood, will obviate the dangers pointed out above, as I have certificates from several of the most respectable persons concerned in coal-mining, who spontaneously conferred these kindnesses upon me. Nor have I in any instance experienced the least opposition to my views, and the application of my discoveries, for preventing accidents. Several eminent persons concerned in the management of coal-mines, and who have not yet tried my new safety-lamps, have given me upon inspection their approval of them in the most satisfactory terms, and I have reason to expect that in addition to those first-rate coal-mines in which my safety-lamps have been tried, approved, and used effectually, managers of other coal-mines will, as may seem suitable to their convenience, adopt them. I may remark, *en passant*, that when the wire gauze in a Davy-lamp is more open in its texture than in the proportion of twenty-eight to thirty, in both warp and woof, as Davy himself proved, we shall find that the invisible flame will, by such apertures or meshes, be permitted to be formed outside the wire-gauze cylinder, which cylinder, in that case, cannot be considered a barrier to the progress of flame. Here, "cooling power" is out of the question, and, as in all other cases, does not afford the true explanation of the phenomenon.

As I have not drawn up this paper for the perusal of the learned readers of *THE LANCET*, in order to show the value of my new safety-lamp, but for the advancement of science, I will conclude by remarking, that by the use of my new safety apparatus, all the contingencies which are mentioned above in respect to the Davy may be avoided; and as the Davy is in general use in the coal-mines of the north of England, I considered it imperative upon me to add to the Davy in use the safety shield, so that the expense of new safety-lamps may be avoided. I am informed by all persons using my safety-lamps, that the wire which I employ for supporting the safety cylinders, stands to their satisfaction, when placed over the flame of the oil-lamp in the wire cage, but the moment fire-damp burns within the cylinder of wire gauze, the piece of fine wire is fused, and the whole cage is instantly surrounded by the safety cylinders. Sunderland, Nov. 5. 1835.

The printed Minutes of Evidence, and the Report of the Parliamentary Committee appointed to inquire into the lamentable catastrophes which are so constantly occurring in the *Mines* of Great Britain, with the view of ascertaining the means of preventing the recurrence of similar accidents, have just been issued. We shall shortly examine some parts of the document, which extends to 360 folio pages.

ON THE LAW OF MORTALITY

IN

EACH COUNTY OF ENGLAND.

By T. R. EDMONDS, Esq., B.A., of Trinity College, Cambridge.

THE knowledge of the laws which regulate the collective vitality at different ages of the population in various districts of England, is evidently an object of the highest interest to physiologists. When those laws are established, and when the peculiar circumstances of each locality have been investigated, we may reasonably expect soon to arrive at a knowledge of some of the chief causes affecting the prolongation of human life. Having minutely examined the great mass of facts accumulated in the *English Population Returns* of the years 1821 and 1831, I can speak with confidence of the high value of the information which they contain. The results from one hundred separate observations of males and females, are consistent with each other, and in harmony with previous observations, when viewed in connection with the new theory of mortality which I have explained in Nos. 605 and 614 of *THE LANCET*. There exist, however, in different localities, considerable variations in the mortality at different ages, and in the relative mortality of the two sexes. The causes of these variations, whether dependent on atmospheric or other external circumstances, or whether dependent on original peculiarities of individual constitution, is a subject well worthy to exercise the ingenuity of physiologists.

Before proceeding to the general investigation of the subject, it may be interesting to state a few of the principal results hereafter to be established. In comparing together different counties, the characteristics of each peculiar law of mortality are marked by the mortality in three principal divisions of age; namely, in the period under five years of age, in the period between fifteen and sixty, and in the period above sixty years of age. In all counties, out of a given number living above the age of sixty years, the number dying in one year is nearly the same. In some counties the mortality between the ages of fifteen and sixty years is nearly half as much greater than in many other counties. In some counties, out of a given number born, nearly twice as many die under the age of five years as in some other counties. In all counties the mortality of males under the age of fifteen exceeds the mortality of females under the same age, in the proportion of nearly 100 to 90.

In the majority of counties, at ages greater than sixty years, the mortality of males seldom exceeds that of females more than three per cent. In the majority of counties the mortality of males between the ages of fifteen and sixty years is *less*, in a small degree, than the mortality of females. The most remarkable result presented by the population returns, is the fact that all the counties wherein the mortality of females between the ages of fifteen and sixty years is at a maximum, are found on or near the same straight line. A low mortality between the ages of fifteen and sixty years is the best index of a healthy population, because the individuals of this class are of much higher political value than the individuals under five years or above sixty years of age. As an index to the healthfulness of a locality, the law of female mortality is to be preferred to that of males, because the various occupations of the latter may exercise an important influence on the mortality. The line of greatest mortality of females between the ages of fifteen and sixty years, is a central one, running in a north-west direction from Brighton to Liverpool. The most healthy counties are those most distant from this line, with very few exceptions.

The materials on which the present observation is founded consist in a return of the ages of the *dying* in all England and Wales during the eighteen years 1813-30, combined with one enumeration of the *living*, and their ages made in the middle of the year 1821. The only important defect in these materials is the omission of a considerable and uncertain number of deaths. The returns made show the number of deaths which have been entered in the parish registers only; and we are left with very little information respecting the numbers omitted through negligence, or omitted because buried in the grounds of dissenters, or in private burial-grounds. Mr. Rickman, who compiled the returns, estimates the deficiency in the deaths to be 8 per cent. less than the true number for the whole of England and Wales. The results which I am about to give for thirty-nine counties of England, are founded upon the assumption that the registered deaths are deficient ten per cent. from the truth. I have supposed that, out of every twenty deaths which have occurred, one is omitted through negligence, and another because the burial occurred out of the church grounds. In the counties of Middlesex, Surrey, Monmouth, and in Wales, I have estimated the deficiency at 20 per cent.; Mr. Rickman having expressed his opinion that the deaths are more deficient in these than in other districts. The consequent deficiency for the whole of England amounts to 12½ per cent. The estimate of Mr. Rickman, however, of the number of deaths which I have assumed as the true total, differs

from the total assumed by Mr. Rickman only one-twentieth part.

It is certainly highly desirable that the number representing the absolute annual mortality at all ages should be correctly ascertained. I believe it to have been ascertained within 5 per cent. of the truth. But even if it should prove defective to the amount of ten per cent., the value of the results hereafter stated will be very little affected thereby: for they would in that case equally well indicate the *relative* mortality at different ages of life, and in different localities, which is the only important question to physiologists. The materials supplied enable us to establish, beyond dispute, the relation subsisting between the mortality at one interval of age, and the mortality at every other interval of age. If the absolute mortality at any one age, or at all ages, in the aggregate be known, the absolute mortality at every interval of age is also known.

In order to obtain the law of mortality prevailing in each county of England during the eighteen years 1813-30, the facts requisite are, the total number of deaths occurring during that period, distributed in quinquennial or decennial gradations of age, together with the mean population who have been alive during this period also distributed according to the same intervals of age. Dividing the number who have *died* in any interval by the mean number who have *lived* in that interval, we obtain the exact number who have died in eighteen years out of a given number constantly living in that interval. A series of numbers thus obtained for each consecutive interval of age would represent the true law of mortality of the population observed. Dividing the results by eighteen, we should have the law expressed for one year, in which form it is most easily compared with the results of other observations. If the results be also multiplied by 100, we should arrive at that form of expressing the fact which is adopted by the best authorities. For example, in the following table the mortality of females in England and Wales, during the eighteen years 1813-30, between the ages of fifty and sixty years, is stated to be 2·16, which is intended to represent the fact that this is the average number of deaths occurring annually for every 100 persons constantly living between the ages of fifty and sixty years. If the materials had been perfect, this number would have resulted from dividing the dying 132,918, by the living 352,160, and dividing the quotient by 18. The result of these operations however is 2·10, which differs from the number above stated, in consequence of necessary correction having been introduced for defects in the materials.

Having stated the nature of the materials as they would be if they were complete, it remains to state the degree and manner in which they are defective from the true

standard. The most important defect, arising from a considerable proportion of deaths not being entered in the parish registers, has been already alluded to. This defect concerns the absolute mortality only at each age, for it may be presumed that these omitted deaths would have been distributed according to age, in the same manner as the total of deaths whose ages are specified. If the defect at all ages be assumed to be $12\frac{1}{2}$ per cent., the defect at each age will also be $12\frac{1}{2}$ per cent. Two minor defects in the materials consist in the want of specification of the ages of a small proportion of the total number returned as living and as dying. The ages of one-eighth of the living population, and of one twenty-fifth part of the registered deaths, have not been specified. The correction necessary on these accounts at each age, is the same as for the total at all ages. In addition to these unavoidable defects, the enumeration of the male sex is defective, by the entire omission of the ages of the military and maritime population, and we have no information given respecting the total numbers of this large class, resident in, or attached to, each county. We are merely informed that the army, navy, &c. belonging to Great Britain, consisted of 300,000 men. This defect ought not to have existed, for it would have been easy to obtain the ages and number of the soldiers and marines resident in England, and attaching them to the summaries of their respective counties. There would probably have existed little difficulty in obtaining a similar enumeration of the sailors belonging to registered vessels. The utility of such an enumeration of seamen would be very little diminished by the fact that the same sailors do not always continue in the same port; because their places are usually supplied by seamen of some other English port, or by foreign seamen. After deducting the sailors and soldiers on foreign stations, I have estimated the amount of that portion which encountered risk of death in England and Wales at 160,000, so distributed that 100,000 are below thirty years of age, and 60,000 between the ages of thirty and sixty years. The effect of this correction, is to reduce the apparent mortality of males at all ages, from 2.23 to 2.17 per cent. per annum.

In the present inquiry, one of the two essential facts to be ascertained, is the mean number who have been alive at each interval of age, during the period of observation, or during the eighteen years 1813-30. The true mean population would certainly be indicated by eighteen annual enumerations of the living at each interval of age. Four enumerations of the living and their ages, made at intervals of six years, would, however, have been amply sufficient, in the opinions of all qualified persons, to determine the true mean population. But in the pre-

sent case, we have only *one* enumeration of the living, and this made *not* at the best time, and yet there seems no reason to doubt that it is nearly as valuable as eighteen enumerations would have been. It appears to be a fact founded upon experience, that in any extensive population, the increase or decrease of the number living in *each* decennial interval of age, is so uniform throughout a period of eighteen years, that the number living in this interval at the end of the ninth year of the observation, is a mean proportional between the number living nine years before, and the living nine years after. The proof of this fact is contained in the English population returns, by means of a supplementary observation of the mortality in England and Wales during a period of seven years, 1818-21. The results of the observation for seven years, agree exactly with the results of the observation for eighteen years, the mean population at the different ages in each case, being assumed to be the number ascertained to be living in the middle of the year 1821, or in the middle of the respective periods of seven and eighteen years. The absolute mortality during the seven years, was 2 per cent. less at every age than the absolute mortality during the period of eighteen years. The relative mortality in the two cases is identical, as it ought to be if the materials of the two observations were complete; and as there is no reason to suspect the mean population for the period of seven years not to have been correctly assumed, there seems to be no room for doubting that the mean population for the longer period of eighteen years, has not also been correctly assumed.

The present observation would have been more complete, if the enumeration of the living, according to age, had been made at the end of the year 1821, which is the middle of the period of observation. The time of enumeration appears to have been fixed on no settled principles, and it seems to have been a mere accident that the time chosen was so near the time at which the enumeration ought to have been made, in order to render the observed number and ages of deaths for eighteen years of the greatest value. The return of births and deaths is made up to the last day of December in each year; and in order to have the means of instituting any accurate comparison between the population living at any time, and the births and deaths, the enumeration ought to have been made at the beginning or end, and not in the middle, of the year. In defence of this acknowledged error, we are told that the middle, of the year was chosen, because the days were longer! If the population had been enumerated at the year 1821, the number living would have been about $\frac{1}{4}$ per cent. less than the number given in the present return. It is necessary on this account, to reduce the ap-

parent mortality of females at all ages, from 2.083 to 2.167.

The scale of relation connecting together the mortality at different ages in large towns, is of a totally distinct character from that applicable to the general population. The relative mortality of the two sexes is also widely different. In the country, the mortality under the age of five years, is only ten times as great as the mortality between the ages of ten and fifteen years; whilst in large towns, it is fifteen times as great. In the country, above the age of five years, the mortality of males exceeds by a very small amount the mortality of females; and between the ages of ten and fifty, the mortality of females even exceeds that of males. But in large towns at every interval of age, the mortality of males considerably exceeds that of females. For the whole of England and Wales, I have assumed that the registered deaths are to be increased 13.947 per cent. for males, and 13.894 per cent. for females, in order to obtain the true number of deaths.

For large towns, I have assumed the necessary increase to be 20 per cent. for each sex; it having been always supposed that the deficiency is considerably greater in towns than in the country. If a lower degree of disparity had been adopted, the minimum mortality, or the mortality between ten and fifteen years of age, would have been less in large towns than in the whole territory. The population returns contain observations on six towns only, which are of the largest size, and which contain a large proportion of sailors and soldiers, of which no enumeration has been made. Having no materials for making a satisfactory estimate of the deficiency, I have made no correction of the apparent results; so that the mortality of the male sex in the six towns between the ages of fifteen and sixty years, is represented considerably higher than the fact. Instead of 3.39 for the mortality of males at all ages, the true number ought probably to be near 3.15.

TABLE, exhibiting the Materials from which the Law of Mortality of the aggregate Population of England and Wales has been deduced.

Between Ages.	Living on 28th May, 1821.				Dying in 18 years, 1813-30.			
	In England and Wales.		In Six Large Towns.		In England and Wales.		In Six Large Towns.

The apparent mortality of males in all England and Wales, has been diminished by .09 between 20 and 30, and by .06 between 30 and 60 years of age, on account of the unenumerated maritime and military population. In the six large towns a greater correction is necessary, but none has been applied.

It might be supposed probable that the mortality deduced for females between the ages of fifteen and fifty years, may be subject to error from the disposition of females to understate their ages. The error is apparently of very small amount. If the ages of all the females, dying as well as living, be understated to the amount of two years, the mortality at each of the three decennial intervals from twenty to fifty years will be five per cent. higher than the fact. But if the ages of the dying are correctly given, and the ages of the living only are understated, then the apparent mortality between thirty and forty will be correct; whilst the mortality between twenty and thirty will be lower, and the mortality between forty and fifty higher than the truth. Adopting the intermediate supposition that the ages of the dying are understated to only one half the amount that the ages of the living are, the female mortality under the age of forty will be very nearly correct.

It has been already remarked, that the numbers representing the absolute mortality at each age in my present tables, are founded upon the assumption that the registered deaths are deficient twelve per cent. from the truth, and that Mr. Rickman has estimated this deficiency at eight per cent. The estimate of Mr. Rickman is not founded upon any fact, and leads to results contra-

dictory of facts which he admits. My estimate is founded upon a probable fact, and leads to results in harmony with all other stated facts. Mr. Rickman agrees with me in supposing that the increase of the English population is entirely due to the excess of births over deaths, or that the immigration from Ireland compensates the emigration from England. Assuming this as a fact, the truth of my estimate and the error of Mr. Rickman's are easily demonstrable by means of the proportion stated to exist between the unregistered births and deaths.

In the population inquiry, questions were addressed to each clergyman requiring an estimate of the number of births and deaths in his parish unentered in the register. A portion of the clergy made such an estimate, another portion offered no estimate. The absolute number of "unentered" births and deaths of which there exists an estimate is evidently of very little value, because we are ignorant of the proportion of the total population from which this estimate was obtained. It may, however, fairly be presumed that the proportion of unentered births to unentered deaths would have been the same for the whole, as for this part of the population. This proportion, regarded as a valuable fact, and the supposition that the increase of population is due entirely to the excess of births over deaths, the difference between the un-

entered births and deaths is a known quantity, and the absolute number of unentered births or deaths is known when this proportion is known. Mr. Rickman's estimated deficiency in the deaths is, however, derived from the apparently groundless assumption, that the total deficiency in the deaths was just double the number of which an estimate was returned. Because the partial estimate amounted to four per cent. on the total, he has assumed that if all had made an estimate, the deficiency would have been eight per cent. He then shows, as a consequence of this assumed deficiency, that the unentered births were to the unentered deaths in the proportion of four to one. He entirely disregards the fact elsewhere stated, that the unentered births were to the unentered deaths as two to one, which proportion would have indicated a defect of twenty per cent. in the deaths, as I have shown in No. 611 of THE LANCET.

For the whole of England and Wales the partial estimate of the different clergymen indicates that the number of unentered births was just twice as great as the number of unentered deaths. If London be excluded, the proportion between the unentered births and deaths was that of three to one. This last proportion I have adopted as true for the whole of England and Wales, because it is applicable to nine tenths of the total population, and because the estimate for London is not much to be relied upon. The determination of the absolute mortality at all ages being a question of great public interest, it may be useful to exhibit the chain of facts upon which my estimated deficiency in the deaths is founded. I have confined myself to the observations on the female sex, because the increase of the female population is capable of being more correctly determined than that of the male population.

The total number of registered births of females in England and Wales during the eighteen years 1813-30 was 3,129,368, and of deaths, 2,022,366, which yields an excess of births over deaths of 1,107,002, instead of 1,658,202, the true increase of the female population in that time. There remains, therefore, the number 551,200 to be accounted for by the excess of unentered births over unentered deaths.

The total number of "unentered" obtained from those parishes which made an estimate, amounted to 357,168 births and 170,930 deaths of both sexes. For London, the estimate was 40,498 births and 65,934 deaths. Consequently for all England and Wales, excluding London, the partial estimate was 316,670 births and 104,996 deaths; which numbers are very nearly in the proportion of three to one.

It is assumed that the true deficiency of females for all England and Wales amounted to 275,600, then

three times this number, or 826,800, will represent the corresponding deficiency in the births. The difference between these unentered births and deaths is 551,200, the increase of the population to be accounted for as stated above.

The true number of births of females during the eighteen years will then be 3,956,168, and the true number of deaths 2,297,966. The female population alive at the middle of the eighteen years, or at the end of the year 1821, was 6,198,200. Consequently the average annual deaths of females was 2.06 per cent., or one out of 48½. The average annual births of females was 3.55 per cent., or one out of 28. The deficiency in the births amounted to 21 per cent., and the deficiency in the deaths to 12 per cent. According to Mr. Rickman, the deficiency in the births was 19 per cent., and in the deaths 8 per cent. According to my estimate the proportion existing between the total births and deaths of females is that of 172 to 100: according to Mr. Rickman the proportion is that of 175 to 100.

The population returns of 1831 abound with contradictory statements made by Mr. Rickman, founded upon the obviously false hypothesis of the population having been "stationary," and that the annual births had been equal to the annual deaths for a long period of time. Mr. Rickman does not appear to have thought that there was any absurdity in supposing 175 to be equal to 100. At a late hour, and since the publication of the returns, he has been made sensible of his error. In the pages of a medical periodical he has recently bestowed a great deal of unnecessary pains on the demonstration of his own errors. He appears to claim praise for detecting errors which could never have been committed by one possessing any knowledge of the subject discussed. He is greatly mistaken if he supposes that any writer of repute has said a word to the effect that the "hypothesis of the population being stationary," was applicable to circumstances like those of the English population. One specimen of Mr. Rickman's conclusions will be sufficient to satisfy the reader as to their value. Because out of 100 deaths of females in England and Wales at all ages 32 occur below the age of five years, he has stated as a fact that out of 100 born, 32 die before they complete their fifth year. The true statement is, according to his own showing, that 32 die out of 175 born, which represents a mortality of 184 instead of 32 per cent.

I have considered it unnecessary to construct a table rigorously representing at annual intervals the law of mortality which occurred in England during the period of observation. Such a table would be of very little value, because it would differ in an insignificant degree from a theoretical table

which I published more than three years ago. Moreover, there is reason to believe that this theoretical table being founded upon general principles, will be a better indication of future facts, than a table exactly representing one fact out of a great series of facts. The mortality of the female population of England is represented as near the truth as can be desired for any useful purpose, by my table of "Mean Mortality," when the limiting age of the period of "infancy" is taken at seven years. In the published table I have fixed this limit at eight years, which is the true limit for the male population of England. To adapt this table to the female population no alteration has been made except at ages under eight years. The results of this altered table agree very nearly in three important points with the results of the English observations for females. According to the table and according to the fact, the mortality between the ages of five and ten years is 20 per cent. greater than the mortality between the ages of ten and fifteen years. According to the table, there die annually 4.47 out of every 100 constantly living under the age of five years. According to the fact, when the registered deaths are assumed to be deficient 12½ per cent., the mortality of females under the age of five years was 4.60 per cent. According to the table, out of 100 born 19.5 die before they complete their fifth year of age. According to the fact when the registered births are assumed to be deficient 21 per cent., out of 100 born, 19 die before they complete their fifth year. The near coincidence of these results is satisfactory evidence of the general consistency of the materials, and of the conclusions deduced from them. It may be useful to state that the "expectation" or mean duration of life, at birth is 43.70 years according to the table of Mean Mortality, when the limit of "infancy" is fixed at seven years. If the English female population had been stationary, or if the annual births had been equal to the annual deaths for a long period of time, there would have died annually at all ages during the eighteen years 1813-30, one out of every 43.70 living. But on account of the increase of population, the actual annual mortality was only one out of 48½.

On the supposition that the registered deaths are deficient 12½ per cent., the mortality of the English population between the ages of sixty and seventy, and between seventy and eighty years of age, agrees very nearly with that of the table of Mean Mortality. According to this table, 204 living between the ages of sixty and seventy are reduced by deaths in ten years to 100 living between the ages of seventy and eighty years. According to the fact stated in the returns of 1821, there were of both sexes 201 living between sixty and seventy for every 100 living between seventy and eighty

years. If the population had been stationary between sixty and eighty years, the coincidence of these numbers would prove that the absolute mortality at this interval has been truly stated, and is represented by the Table of Mean Mortality. If the absolute mortality is correctly stated at any one interval, it is correct at every interval of age, because the scale of relation connecting together the mortality at different ages is indisputably established. That the population was stationary at the period in question, or that the living in 1821 between the ages of sixty and seventy proceeded from the same number of births as the living between seventy and eighty, appears to be highly probable. At least this was certainly the case in London, and there is no ground for supposing that the rest of England did not resemble London in this respect. Those living in 1821, between the ages of seventy and eighty years, were born in the ten years 1741-50, and those living between the ages of sixty and seventy were born in the ten years 1751-60. Now, according to the London Bills of Mortality, during the ten years 1730-39, the number of baptisms amounted to 170 thousand. In the ten years 1740-49 they amounted to 116 thousand; in the ten years 1750-59 they were 148 thousand; and in the two following decennial intervals the baptisms amounted to 160 and 173 thousand respectively. It may hence be inferred as highly probable that the English population in 1821 was decreasing between the ages of eighty and ninety years, stationary between sixty and eighty, and increasing under the age of sixty years.

The new theory of mortality is founded upon the discovery of three numbers, respectively presiding over three well-marked periods of human life—before, during, and after, the existence of the procreative power. To construct a theoretical table, the absolute mortality at any one age must be known, together with the position of the inferior and superior limits of the "procreative period." In every population, whatever may be the absolute mortality, the relative mortality at different ages is the same, when the position of these two limits is the same. In the Table of Mean Mortality I have fixed the superior limit at the age of fifty-five years, which happens to be the true limit in each of the nine independent observations above stated. In all these observations, and in every county of England, the mortality between fifty and sixty is to the mortality between forty and fifty years, in the proportion of three to two, as it is also in the Table of Mean Mortality. Notwithstanding this extensive coincidence, the position of this limit is not to be regarded as having more permanency than the position of the inferior limit. A variation of a year in the position of the superior limit involves a change of five

tive mortality; the same variation in the position of the inferior limit involves a change of 32 per cent. in the relative mortality. In constructing the Table of Mean Mortality, I ventured, in opposition to all direct evidence on the subject, to put back the inferior limit one year, and thus effected a diminution of 32 per cent. in the relative mortality under the age of nine years. My prediction has been confirmed, and more than confirmed three years after its publication, by the present observation on the English population. According to all previous observations, the inferior limit, or the mean age of attaining the minimum mortality, was at nine years—the mortality between five and ten years being always twice as great as the mortality between ten and fifteen years of age (as it is now in the large towns of England), which agrees with theoretical tables wherein the inferior limit is fixed at nine years. In the table of "Mean Mortality," I assumed the inferior limit to be at the age of eight years, which is the limit now applicable to the total male population of England; the mortality between five and ten years being 50 per cent. greater than the mortality between ten and fifteen, according to fact and according to the table. But for the female population the limit is at the age of seven years, for the mortality between five and ten is only 20 per cent. greater than the mortality between ten and fifteen, according to fact and according to a table wherein the age of seven years is assumed as the limit. In Belgium the position of this limit is now at the age of eight years and a quarter for both sexes. The grounds of my accomplished prediction were the following:—From the ages of the living under fifteen years, and from the rate of increase in the births, indicated by the population returns of 1821, I became convinced of the fact, that the mortality under the age of ten years was less in an extraordinary degree than had ever been supposed to exist. I knew also that the diminution in the mortality during infancy was amply sufficient to account for the reduced mortality in England at all ages. Knowing then that the mortality was considerably diminished under the age of ten years, and not diminished above that age, I accounted for it in the only way consistent with the new theory. The truth of this theory has now been confirmed by the highest order of human evidence, for it has enabled me to predict the precise manner in which a new and extraordinary diminution of the relative mortality in infancy has been effected.

In every county of England the proportion of deaths occurring at annual intervals between the ages of one and six years, agrees with what I have stated to be the universal law. The deaths in any two age are always in the proportion of two, according to fact

and according to theory, as may be perceived by any person without calculation. Under the age of one year, the theory is correctly applicable to the county of Cornwall only. In all other counties, the proportion of deaths under the age of one year is much greater than that indicated by the theory. Four years ago, in the preliminary observations to my "LIFE TABLES," I expressed an opinion that the theory would not represent the fact in all cases under the age of eight weeks. I believed then, as I believe now, that the high mortality under the age of one year will be found to consist in an excessively high mortality during the few weeks immediately succeeding birth.

As the subject which I am discussing naturally divides itself into two parts at the point now attained, I shall here arrest my remarks until the publication of another Number of THE LANCET will admit them to appear.

46, Regent Square, Nov. 7, 1835.

CASE OF

GANGRÆNA SENILIS,

IN WHICH THE POST-MORTEM EXAMINATION DISCLOSED A

COAGULUM OF FIBRINE ADHERENT TO THE AORTA.

To the Editor of THE LANCET.

SIR.—If you consider the outlines of the following case worthy of being recorded in your truly independent journal, I shall feel obliged by its insertion. It is, in my opinion, calculated, in some degree, to illustrate the pathology of a disease which is too frequently fatal.—I am, Sir, your obedient servant,

W. TAGERT,
Surgeon to Mercer's Hospital,
Dublin.

CASE.—Catherine Strahan, aged 66, of a delicate and feeble frame, was admitted a patient into Mercer's Hospital, on the 25th of September, 1835. She then suffered from distressing diarrhoea, and complained much of pain in the left leg and foot, accompanied by a constant sense of coldness. This coldness, and the pain of the extremity, with occasional diarrhoea, afflicted her about a month previous to her admission. The pain was so urgent as to interrupt her sleep. She attributed her sufferings to rheumatism, and kept the limb wrapped in flannel. She did not suffer from pains elsewhere, but her general health was broken. On admission, the leg and foot presented a natural appearance, and she stated, that when suffering from cold, the limb assumed a livid hue. The diarrhoea was relieved by the ordinary

treatment, but the pain and uneasiness of the limb continued unabated, and became daily more urgent. On the 1st of October, almost a week after her admission, a darkish livid hue was observable on the integuments of the left instep, which felt colder to the touch than the opposite one. This lividity soon extended to the outer ankle, and, after two or three days, involved the entire foot. At this period there was no sign of vesication about the toes. On examining the femoral artery in the groin, a slight thrill could be distinguished. Its pulsation was evidently weaker than was the pulsation in the opposite limb. The pain was now very severe, with nocturnal exacerbations. The extremity was wrapped in cotton, and oiled silk was placed outside this, and anodynes were administered to alleviate her sufferings. The lividity extended up the limb, day after day, and vesications soon formed on the leg and foot, from which there was serous oozing. The gangrenous appearance now occupied the entire limb, almost to the knee, but evinced no disposition to extend higher, for about ten days previous to her death. I may observe, however, that an isolated gangrenous spot appeared over the patella, and in three days afterwards the thermometer indicated the following temperature:—

Heat of the ward, 68°;

Heat of the sound limb, 82°;

Heat of the gangrened limb, 74°.

At this period no pulsation could be distinguished in the femoral artery at the groin.

It is unnecessary to give a minute detail of the daily treatment pursued. It will be sufficient to observe, that it consisted principally of the internal exhibition of the acetate of morphine, with a cautious administration of wine and stimulants, combined with tonics, the extreme debility and unceasing pain being the prominent indications. She sank gradually under her sufferings, which terminated in death on the 22nd of October, nearly one month from the period of her admission into the hospital. The diarrhoea had returned, and continued unchecked for a few days previous to her decease, notwithstanding the use of the cretaceous mixture, with kino, opium, and other astringents.

Autopsy, ten hours after Death.

Nothing remarkable was discernible either in the thoracic or in the abdominal viscera. In order to examine the large arterial trunks, I had the aorta carefully removed, together with its continuation into the common iliacs, and also the entire of the main arterial trunk of the diseased extremity, with a portion of the internal and external iliacs of the opposite side. On slitting up the aorta, its coats appeared to be healthy in the thoracic region; the internal coat of the abdominal aorta presented a number of whitish spots, of an irregular

figure, which were slightly elevated, containing an earthy or ossaceous deposit. This atheromatous deposition was external to the lining membrane, and unaccompanied by any inflammatory appearance. The aorta at its bifurcation was occupied by a coagulum of fibrine, of a conical shape, three inches in length. The base of the cone was turned from the heart; its colour was a yellowish white, without a trace of red colouring matter; it was firm in consistence, resisted strong pressure with the finger, and gave to the vessel a solid fleshy feel before it was slit open. It was intimately adherent by its base to the entire circumference of the artery, and could not be removed without tearing the bond of union. The organization of the coagulum was so perfect, as fully to demonstrate that it had existed during life, and had been possessed of vitality. The apex of the coagulum was also adherent to the aorta. Its base, for the extent of more than an inch, blocked up that vessel, and, immediately above its bifurcation, filled the cavity of the aorta so completely as to act as a perfect barrier against the transmission of blood through that portion of the vessel. Coagula of a similar appearance, but not adherent, occupied both of the common and internal iliacs. The external iliac of the right side was healthy, and unoccupied by coagulum. That of the opposite side contained a fibrous plug. The femoral artery of the diseased side was much contracted in its entire course, even to the ham, and was occupied by coagula of a reddish-brown colour, but of firm consistence. High up in the groin, near Poupart's ligament, the coagulum was intimately adherent to the artery. The popliteal was much contracted, and the posterior tibial was so diminished in size, that it could with difficulty be recognised; it contained no coagulum; the muscles of the gangrened limb were much softened, and were dark in colour. The aorta, and the remainder of the arterial trunk, with the coagula *in situ*, I have preserved in the museum at *Mirrer's Hospital*.

Remarks.—With regard to the question, Was the coagulum of fibrine found in the aorta a post-mortem deposit, or did it exist during life? I have to state, that, independently of any reference to the history or symptoms of the case, I think its existence during life is fully proved by the fact of its organized connection with the artery. It may also be asked, Were the coagula the cause or the effect of the gangrene? Upon this point I shall refer to the following extract from "*Andral's Pathological Anatomy*." After speaking of the various ways in which an artery may become obliterated, it makes the following remarks:—

species of obliteration (that is by coagula of fibrine) has been more frequently observed than the first, but no instance of it has as yet been seen in the aorta; it has been repeatedly found in the arteries of the lower extremities, coinciding with the disease known by the name of gangrena senilis, and it is reasonable to conclude that in these cases the obliteration of the arteries is the cause of the gangrene. This much at least is certain, that it is not the effect; for in a patient who died of gangrene in one foot, and in whom all the arteries of that limb were completely obstructed by solid coagula of fibrine, the commencement of a similar obstruction was found in the arteries of the opposite limb, although not a sign of gangrene was observable in it. It appears to me highly probable that if this individual had lived for some time longer, the arteries of the sound limb would have become more and more obstructed, and that the foot of that side would then have become gangrenous."

The following passage from Dr. Thomson's excellent work on inflammation may not be considered out of place here. In the article "Mortification," he says, "Fabricius Hildanus mentions a case of mortification of the feet and legs which proved fatal to a man in the vigour of life, and of apparently sound constitution, in whom after decease a scirrhus tumour was found surrounding and compressing the inferior cava and aorta, just where they are about to divide, to form the iliac vessels, and which by its pressure had prevented the free passage of the blood to and from the lower extremities."

Beclard also was of opinion that the obliteration of the arteries was the cause of the gangrena senilis, as will appear from the following extract from his "Elements of General Anatomy":—"Contraction and obliteration of the crural trunk and its branches. This is the ordinary cause of the gangrene of the toes, feet, and legs, in old people, the change happening in a part, and at a period, when the arterial twigs themselves, affected by induration, are no longer capable of the rapid augmentation necessary for the establishment of a collateral circulation."

I shall not trespass further on your valuable space than just to observe that I lately witnessed the dissection of another female who died of the same disease, and in whom there were found most extensive ossific deposits in the thoracic and abdominal aorta, as well as in the artery of the affected limbs. In this case also the posterior tibial artery was so diminished as to be found with diffi-

EXCESS OF

FATTY MATTER IN THE BLOOD.

DEFICIENCY OF THE RECTUM.

To the Editor of THE LANCET.

SIR,—I send you two cases of unusual occurrence, the first recommended from the remarkable milky appearance of the blood; the second being a case of imperforate anus, with deficiency of the rectum. By giving them insertion in your valuable journal, you will oblige your obedient servant,

THOS. ROBT. TATHAM, Surgeon.
Huddersfield, Nov. 27, 1835.

CASE.—April 25th, 1833.—Mr. William Bond, ætat. 36, publican, of a florid complexion, rather corpulent, and of a sanguineous temperament. I found him suffering from a severe catching pain in the right hypochondrium, much aggravated upon pressure, on the slightest attempt to take a deep inspiration, and also increased by the recumbent posture. He had headache, the countenance was flushed, and there was a suffused redness of the eyes, tongue furred, dry in the centre, much thirst, surface hot and dry. Pulse 136, full and hard; urine high-coloured; bowels confined. Says he has not been quite well for the last fortnight, having suffered from loss of appetite, disagreeable taste, and "greasy" eructations; did not vomit; complains that his vocation exposes him more to the influence of liquor than is consistent with health.

V. S. ad deliquium animi. Thirty ounces were taken.

R. Calomel. gr. xij; Pulv. Opii gr. iij.
Cons. q. s. Divide in pilulas vj.
Capt. 3tiis horis.

R. Mistur. Effervescentie, sumend. 3tiis horis.

P.m. Pain in the side much relieved, breathes with tolerable ease, can lie down in bed without inconvenience, but cannot take a deep inspiration without pain; skin become moist; pulse 130, softer. The blood as it stands, undisturbed, appears like thick custard; the coagulable lymph on the crassamentum is a quarter of an inch thick, and the serum has precisely the appearance of milk. These peculiarities induced me to submit it to the inspection of Dr. Walker and Dr. Turnbull, physicians, of this town. Dr. Walker visited the patient with me on the following day. Upon drawing off the serum from three teacupfuls of this blood, leaving the crassamentum behind, and mixing with it half its volume of sulphuric ether, it yielded, upon evaporation, upwards of two drachms, in weight, of fatty matter, of the consistence of butter.

26. Improving; pulse, 126; lateritious sediment in the urine; bowels have not yet been opened. *R. Ol. Ricini ʒvj, statim sumend. et rep. 6tis horis, si opus sit.*

27. Two doses of the oil produced three dark-coloured and offensive evacuations.

May 3. Convalescent. During the last few days more active cathartics were administered, which have restored the healthy appearance of the evacuations.

CASE.—January 16, 1835.—I was sent for by Mrs. Whitworth to examine her male infant, born on the 14th inst., which she had just discovered had an imperforate anus. The infant had been indisposed from its birth, and refuses the breast and all nourishment. It is very restless, almost constantly crying, holds itself stiff, turns blueish, and appears to be threatened with convulsive fits. She attributed these symptoms to uneasiness in its bowels from its not having had an alvine evacuation. The greenish slimy appearance of its urine upon the cloths, led her to make an examination, when she discovered an absence of the natural outlet from the bowels. The raphe, from the scrotum, is continuous through the perineum. There is no vestige of an anus, no doughy feel, nor any sense of fluctuation on making pressure over the parts. Mr. Robinson, surgeon to the *Huddersfield Infirmary*, accompanied me in the afternoon to see the patient, when we decided upon an operation without further delay. I commenced by making an incision in the line of the raphe a little below the scrotum, and carried it rather beyond what I supposed to be the proper situation of the anus. This incision might be an inch and a half in length. I then carefully dissected backwards, to avoid wounding the urethra and bladder, and downwards, towards the sacrum, full one inch from the surface of the perineum, before I reached the gut, which was much distended, the infant forcing very much the whole time. I made a free cut into it, which was followed by a very copious discharge of meconium. I then passed with the greatest ease, and without apparent increase of pain to the infant, my left forefinger into the colon. Oiled lint was placed in the opening. Very little blood was lost in the operation, but blood oozed much during the night. The child, however, continued hearty, and par-took freely several times of arrow-root.

February 1st. Doing well. Fed with the spoon; the mother could not get it to suck, and her milk has now disappeared. A little oiled lint, and simple ointment on lint, were used during the first five or six days. Afterwards I made a bougie of tolerable size, and covered it with wax, which is introduced three and four times a-day, allowing it to remain for a quarter of an hour or twenty minutes each time.

10. Up to this day the infant continued

to do well; it has made water in natural quantity, quite clear from fecal matter, and passed its stools without much inconvenience. The use of the bougie has been diligently persevered in three and four times a-day; nevertheless the parts have contracted rapidly. Passed per urethram this morning a quantity of fecal matter. Phymosis has come on; the scrotum is slightly ery-matous; and the perineum is inflamed, swelled, and painful. Bowels rather confined; dejections of a pipe-clay appearance. In consequence of the inflamed state of the parts I desired them to desist from using the bougie for a day or two, and ordered a zinc lotion to be applied to the affected parts, and a dose of castor-oil, and some alterative powders to be taken twice a-day.

13. Much the same; the oil operated freely, takes scarcely any nourishment, very restless; there is now much purulent discharge from the urethra.

15. Takes more nourishment; parts less inflamed; bowels more regular; the bougie is again used, a little bloody discharge follows each introduction.

19. Rests better and takes more food; yet is weaker, and more attenuated; the urethral discharge continues not so severe; the phymosis and œdema of the scrotum have subsided. Dr. Walker and Mr. Robinson called this morning, but suggested nothing that could be of decided relief. The mother, of her own accord, has given it, during the last few days, a little Godfrey's Cordial.

26. Much the same; discharge of fecal matter, *per urethram*, continues daily; scrotum very much relaxed; screams violently at every attempt to make water; the introduction of the bougie causes spasm of the bladder, and a flow of urine,—bloody mucopurulent discharge following its removal.

March 15. Continues to decline; is much more attenuated; the appetite is variable, sometimes very voracious; the artificial opening is more contracted; the other symptoms are as before noted.

20. Dead.

Autopsy on the 21st; Dr. Walker and Mr. Robinson present.—Body very much emaciated; thoracic viscera healthy. On opening the abdomen, the omentum was found nearly free from fat; the large bowels were greatly distended with air; liver much shrunk, small intestines of a shrivelled appearance; stomach and mesentery natural. I detached the scrotum and penis, with the corresponding integuments, from the pubes, carefully divided the symphysis, and separated the bladder from its connection with the inner surface of those bones. Passing a director through the urethra into the bladder, and slitting it open superiorly, I found the opening to be a small narrow canal, a quarter of an inch in length, situated immediately behind the prostatic part of the urethra, and communicating with the bladder.

extremity of the colon. The gut contained a little bloody mucopurulent matter, and curdled feces; it had descended to within half an inch of the surface of the perineum. This portion, judging from the appearances, would soon have been in a highly diseased state.

MODIFIED SMALL-POX

OCCURRING

TWENTY-TWO YEARS AFTER VACCINATION,

Turning on the third day after the appearance of the Eruption.

To the Editor of THE LANCET.

SIR,—I beg to send you the following case for publication.—

J. S., *ætat.* 51, of short stature, and well formed, possessing general good health, and having scarcely ever known, as he states, "what it is to be ill," was seized with a sharp attack of fever, attended with severe headache, which he attributed to cold. A dose of calomel, and an aperient, relieved him, but he was unable to quit his bed, on account of debility and giddiness, for ten days, during which period there was occasional remission of the febrile symptoms, which on the sixth day assumed the intermittent form. On the eighth day, two incipient pustules appeared on the hand, succeeded by others on the face and body. I at first imagined these to be varicella, but the number and character of the pustules on the tenth day were unequivocal. The eruptive fever was severe; about a dozen pustules arrived at maturity; those on the hand progressed regularly, but on the face and some parts of the body they died away before the formation of pus. On the tenth day, those which had matured became flattened, and were scabbed on the thirteenth. The patient gradually recovered, and was quite well on the fifteenth day.

On examination of the arm, there appeared two well-defined cicatrices. The vaccination had been perfect, and the patient described it as "a very fine arm." The rise and progress of the pustules were *steady and uninterrupted throughout*. No lymph was taken from them, and to this fact I am disposed to attribute his preservation from the disease, which, but for this ægis, would, in all probability, at his age, have terminated fatally.

I am, Sir, your obedient servant,

T. W. WANSBROUGH.

DOUBTFUL SEX.

CANCER OF THE RECTUM SUCCESSFULLY REMOVED.

To the Editor of THE LANCET.

SIR,—I take the opportunity of a friend proceeding to London, to send you two cases which you may consider of sufficient interest for publication.

I am, Sir, your obedient servant,

D. R. RANKIN.

Carlisle, Lanarkshire, Nov. 15, 1835.

CASE 1.—A case of that peculiar conformation which is usually distinguished, however inaccurately, by the term "Hermaphrodite," has lately fallen under my immediate observation, and as it is remarkable in some degree, I shall in the following short description try to bring before the reader as distinct a picture of the case as possible.

The child is about ten months old, healthy in every respect, and well made. The present appearance of the infant, so far as regards the external parts of generation, is much the same in proportion as it was at birth. At certain times, without close inspection, the parts present all the characteristics of the female; the mons veneris is freely rounded, and the labia majora are of the usual dimensions, in the commissure of which the clitoris is merely seen. At other times an opposite appearance is presented; the labia disappear, a scrotum hangs loosely down, and, in place of the clitoris, a penis, small in size, is beautifully displayed.

During the first-described state of the parts, on more minute examination, the labia are found to be covered with integument, corrugated, and in other respects like that which forms the scrotum, and to contain, each, a small moveable oval body, like a testicle. There are no nymphæ; but a fold of integument, reflected from that protuberance which occupies the place of the clitoris, simulates faintly those processes. The body holding the place of the clitoris, has a mucous membrane for its covering, is cylindrical, about three-fourths of an inch long, rather disproportioned in thickness, not unlike, in shape and size, to a large well-formed female nipple, and very much resembles a penis. The glans with its perforation, and the prepuce (short and incapable of covering the glans) with its frenum, are most distinct; but there is no corona glandis, or cervix. Beneath, and at the root of this body, there is a small orifice, which proves to be the proper urethra; and under this, indeed in its proper situation, another opening, the vagina, which, in appearance and depth, is of the normal standard.

In the other state of the parts described,

while the female peculiarities are sufficiently well marked, the male organs are very fairly represented, only the scrotum is divided in the middle, giving a pouch to each testicle, and the penis is short.

The anatomical structure of the penis, or clitoris, in this case, it is not easy to determine; it is, however, an erectile body,—a characteristic of both. While in the erect state, it can be very easily traced to its root, which seems to be over the symphysis pubis—there being no trace of it in the perineum.

The question, Is it male or female? has a hundred times been asked; a question which, in the meantime, cannot be decided positively. Independently of any other consideration, the presence of testicles, with some, decides the matter; but the minute inquirer perhaps will not rest satisfied with such evidence, so long as the functional powers are questionable. May not there be a womb, and appendages, and ovaries too? A near approximation to such a formation has been proved oftener than once, and we do not know what may be the result of further investigation.

CASE 2.—Mrs. —, aged 55, of weakly constitution, was first seen by me towards the end of Nov. 1831. She had for nine months endured a great degree of torture, from pain in the rectum; for the last six weeks she had had discharge from the anus, of very offensive matter, and the pain was now so incessant and severe, that life had become a burden. She had been attended, during the period above stated, by the family surgeon, who supposed that it was a hemorrhoidal affection from which his patient suffered, and treated her accordingly. He had even lately "cut away a blind pile," as he called it, namely, a part of the scirrhus.

On examination per vaginam, a flat, indurated, inelastic body was distinguishable on its posterior aspect, and on introducing a finger into the rectum, and passing it on the anterior aspect, an extensive, irregular, tubercular surface was detected. With the aid of the speculum the whole was brought into view, and the nature and extent of the disease at once seen. The diseased mass, a congeries of tubercles of various dimensions, extended nearly four inches along the anterior of the rectum. It was about two inches broad; the margins were well defined, and the rest of the bowel seemed to possess its integrity. As the only probable means of relieving the immediate sufferings of the patient, and the only hope, however small, of affording permanent relief, or at least of prolonging life, an operation was recommended, Mr. Logan, of Larnark, concurring in the proposal, to which the poor sufferer willingly responded.

On the 29th of Nov., after a renewed and careful examination of the parts, the operation was performed. The recto-vaginal

septum was found two inches thick at the perineum, and, at the superior part of the tumour fully an inch; the coat of the vagina, posteriorly, were greatly attenuated, and proved, at some particular points, to be involved in the morbid mass. It was therefore thought vain to endeavour to preserve it. The patient being placed in a suitable position, the speculum was introduced into the rectum, and so managed that one of the arms ran along the anterior margin of the diseased intestine on the right side, which was the line of the first incision. The knife was passed along the arm of the speculum, while the index-finger of the left hand was introduced into the vagina, to receive, at the highest part of the tumour, the point of the knife, which, guided in this way, was brought freely out at the perineum. The part thus freed on one side, was grasped by an assistant with a long flat forceps, and carried to the right side. The incision on the left side was then made in the same way. The whole diseased portion was now taken hold of by the left hand, and pulled down until the knife easily reached beyond the disease, which was detached by a transverse incision. There was little blood lost, and the cautery was required to be applied only at two points. A sponge, loaded with a weak solution of nitrate of silver, was introduced into the cavity, and the patient put to bed. Setting aside the inconvenience experienced by the involuntary discharge of feces, and the falling down of the womb, no untoward symptoms ever appeared, and the patient now enjoys comparatively good health.

The diseased portion of the rectum, on inspection, presented all the characteristics of tubercular scirrhus. Ulceration had commenced in three different places, and there was one ulcerated cavity large enough to admit a walnut.

EARLY BREEDING IN THE HEIFER.

P.S. I have notes of a few interesting cases, (?) not strictly medical however, which have lately occurred (?) in my neighbourhood. One of an animalcule in the eye of a horse. One of singular monstrosity in the shape of a chicken with *four* legs and *three* wings. And a case of precocious impregnation in the cow species. A bull calf of *less than three months* age, and a quey calf of about *two months*, copulated, and within nine months the female brought forth her first-born; both mother and offspring being yet alive. Will details of any of these phenomena suit the pages of *THE LANCET*? If so they shall be forwarded.

. We find the following statement, by Mr. W. A. Cartwright, of Whitechurch, the *Veterinarian* for November, 1831, on the subject of impregnation in the

"A Mr. Wilson, a respectable farmer, residing at Alkington Hall, had a cow that calved her first calf in January, 1834. When about six months old, this calf was bulled by a bull calf of the same age, when running out with her. In about nine months after she calved very well, and brought a heifer calf which is now rearing. It is rather small but healthy. The breed of this heifer is of the short-horn."

In the same periodical for December, the Rev. Henry Berry, alluding to the above occurrence, makes the following statement. The subject is interesting to physiologists:—

"I this year lost an improved short-horned heifer, from the injury experienced in extracting a calf at a period when the dam was *only thirteen months old*. The bull's access to her at such an early period was of course accidental; but the circumstance of calves seeking the bull at this early age is quite common in my stock, most particularly if the calves be allowed to suck the dam. Strange though the circumstance may seem, I find them more susceptible of impregnation at a very early age than when more matured; and, still more strange, my late but frequent experience has been derived from cases where the calves, unmanageable under these circumstances, have obtained access to a *particularly large* bull, whose size would suggest the impossibility of consummation. I think it probable that *any* calf allowed to suck the dam, would come earlier in season than otherwise, but the improved short-horns are peculiarly characterized by *general* early maturity, and I should, even without the testimony of experience, be inclined to expect the result under consideration, as well as the other indications of such early maturity."

THE LANCET.

London, Saturday, December 5, 1835.

THE excitement in the profession on the subject of the medical contracts which are still being made in the new parochial unions, is on the increase. The dissatisfaction is deep and general, and sincerely do we hope that the indignation of the members of the profession will undergo no abatement, until the vile, the abominable, the brutal system by which the making of these contracts is carried on shall be for ever abolished.

As a member of this Journal we cannot but feel that it was unjust to

condemn the Poor-Law Commissioners, when those gentlemen had expressly declared to Mr. HODGES, M.P. for Kent, and other gentlemen, that the Boards of Guardians should exercise the unrestricted privilege of arranging the conditions of the medical contracts in the new parochial Unions. In offering those exculpatory remarks we relied on the word and promise of the Commissioners,—our reliance was, however, but indifferently founded, if the statements which are contained in the letter of Mr. CEELY, of Aylesbury (inserted at page 387 of this week's LANCET), be supported by a correct apprehension of the circumstances which he has explained. Mr. CEELY does not write anonymously. He is a most respectable and intelligent practitioner, and we place, therefore, the fullest reliance on the details which he has communicated. It would now appear that the charge of interference in arranging the medical contracts between the boards of guardians and medical practitioners, is brought home distinctly and unequivocally to the Commissioners and their agents, and thus the promise which was so unreservedly made to the Kent deputation, has been unfeelingly and unblushingly falsified. It is really impossible to write or to speak on this perverse and cruel exercise of authority, with any degree of moderation or patience. The Commissioners and their agents are resolved, it seems, on reducing the amount of the poor's-rates. "No matter what may be the consequence to the poor,—no matter what sufferings may be inflicted,—no matter what lives may be lost,—THE POOR'S RATES MUST AND SHALL BE REDUCED." Thus would speak the Poor-Law Commissioners. But a declaration of a very different character will be heard from the mass of the people of this country. The conduct of the Commissioners and their agents relative to the contracts, is bringing the Ministers of the Crown into disrepute and odium everywhere throughout the rural districts, and, Heaven knows, a reforming

ministry stand in need of no such depressing auxiliaries in those quarters.

There are, in England and Wales, upwards of *fifteen thousand* medical practitioners, whose occupations necessarily lead them into all ranks of society, and whose learning, usefulness, and integrity of character, render them the objects of universal esteem and respect. Leaving out of consideration, therefore, the protection of the poor, which ought to be the first subject of consideration, can any executive government be justified in suffering their officers to treat with disrespect, contumely, and insult, such a body as is constituted by the members of the medical profession? But we are firmly convinced that neither the Prime Minister nor the Secretary of State for the Home Department has sanctioned any one of the disparaging acts of the Poor-Law Commissioners relative to the medical contracts. When Lord JOHN RUSSELL was addressed on the subject in the House of Commons, he spoke in a tone of the most fervent earnestness, in deprecating any arrangement with medical practitioners, which could have the effect of derogating from the interests of those gentlemen, or of withholding from the poor any essential medical aid in the hour of sickness. The conduct, therefore, of the Poor-Law Commissioners and their assistants must be brought under the consideration of the executive Government, and of Parliament, and we will soon see whether the evil, great as it is, cannot be removed by an efficient and permanent remedy. The course of conduct which the Assistant-Commissioners are pursuing, is calculated to drive the people into a state of fury, of madness. If it be the object of those hired functionaries to *destroy* the poor sufferers, let them have the honesty, the boldness, the courage, to make the acknowledgment; but let them not, under the specious pretext of providing the poor with competent practitioners from a distance, send amongst the wretched and destitute sufferers, a set of VAMPIRES, who

willingly consent to obtain a disgraceful livelihood, by a profuse sacrifice of human life. What offences have the poor of this country committed that they should be deprived of the services of respectable resident practitioners, and be turned over to a set of low-minded mercenary adventurers? Are the meritorious labouring men of England to share a worse fate, with respect to medical aid, than the criminals in our jails? Let us state one fact in order to exhibit the scandalous measure of injustice with which our poor are treated, and the opposite course which can be pursued in the case even of criminals, when *patronage* is to be bestowed. When the "estimates" were before the House of Commons in the last session of Parliament, votes of money were demanded by Ministers, for the supply of medical attendance on the prisoners who were confined in the Penitentiary of Millbank. The number of criminals was under 600,—all, observe, *at hand*,—confined within the walls of a single establishment,—and every prisoner necessarily rendered subservient to the orders of the medical attendant. The Penitentiary is *not an hospital*. There were not five hundred and odd *sick* persons placed there, but six hundred healthy persons, simply exposed to the *casualties* of disease. And what sum was voted by the House as the salary of the resident surgeon? Why, *three hundred pounds*, for one year! And what for the visiting surgeon? *Three hundred pounds* also! These sums, be it observed, were *exclusive* of the charge for *medicines*. Now observe. Medical aid is provided for *criminals*, in a state of *health*, at a charge, per head, of *upwards of one pound per annum*, while the poor labourers in the Unions are provided with the occasional presence of a medical adventurer, at a charge varying from *two shillings* to three shillings and sixpence per annum, and no more,—if he be sick, if he be bed-ridden,—for a *whole year*, and, further, if his miserable mud-hovel be ten miles from the merciless contractor.

Good God! We begin for the honour of our country, when we find atrocities of this description commonly and unhesitatingly perpetrated. It is impossible, utterly impossible, that Ministers can be guilty either of the cruelty or the folly of giving their sanction to such a brutal system. On this point, however, it has become necessary that the most accurate information should be at once obtained.

THE circumstances connected with the filling up of the vacancy caused by the resignation of Mr. KIRBY in the Dublin School, will be stated in the next LANCET in the communication of a correspondent. We have not space on the present occasion, to follow the intriguers through the windings of their crooked and despicable policy, our object being merely to place before the world a specimen of the corruption which forms the staple of a medical corporation. The details, of proceedings of this kind, are worse than imagination can in general conceive them to be. Let the reader assume any ideal standard of turpitude, and he will find it, on examination, to fall far short of the reality of the present proceedings, into which not one useful or equitable object enters. As to the qualifications of the candidates, or the principle of conferring the office on the most deserving competitor, the parties do not even pretend to think, much less to speak. That would be "radicalism" and "revolution." When the *concourse* was proposed some time ago in this Institution, every objection was made to its introduction, on the grounds of its complexity, and the difficulty of carrying it into execution. "Such a plan of disposing of professorships," said the junto, "was perfectly impossible." But what mode of effecting such an object as equal in tumult and intricacy, the plan pursued in the present instance, where we have the elements of discord, and the processes, along with the such contests on the

Members of the College, and the perpetuation of the grossest injustice to the candidates?

THE professor of the "Institutes of Medicine" in the School of Physic in Ireland has been practically illustrating of late the moral of the "little harper in the great theatre." Like the puny musician who mistook the acclamations of his village admirers for the voice of fame, and fancied that the tones of his diminutive lyre would be equally successful in securing the applause of the world upon a larger stage, he has been exhibiting himself, under the impression, no doubt, that the public would repeat the parasitic approbation of the coterie of medical conservatives in the Irish metropolis, and he seems to have had no friend to admonish him of the imprudence of the experiment—no Moliere's old woman to refrain from laughter during the perusal of his vagaries. The course he has adopted is, perhaps, the best calculated to undeceive his self-love, and bring his followers to their senses. It is possible that with his address he might retain their allegiance a little longer—might continue their "consulting physician" and "medico-political advocate" some few months more—were it not for his furnishing them so abundantly with the means of detection.

Let us see how the account stands between these trusty adherents and their disinterested leader. The compact was this,—for it would be idle not to presume a reciprocity of advantages between these honourable individuals—that their liguety should be defended, and their monopoly secured, against the ravages of Reform. Upon one side were expected the brilliant efforts of an accomplished pleader, and the imposing authority of a man of science; on the other the patronage of pupils and of patients, and an annual subscription for "the Journal." But in what have these expectations eventuated? One of the Journals, selected as the mirror for reflecting abroad the beauties of medical science in Ireland, has died a natural death; the other has been preserved from a similar fate by a timely subscription during the recent summer. As refutations of the described condition of medical affairs in Ireland, we have had oracular contradictions;

and in science, the gleanings of continental authors put forward as productions of Irish growth. In physiology we have had fine specimens of philosophy run mad,—and in therapeutics, pleasant juleps and agreeable mixtures. In medical literature, the labours of a Grub-Street compiler,—and in *materia medica*, the commentaries of a confectioner!

By these Herculean exploits were the patronage, the tuition, and the practice, of the medical profession in Dublin, to be secured for ever. Considering the condition of Ireland, and the precedents in other departments, it is not wonderful that the mistake of imitating those examples was made, although, at that very moment, the political monopolies which they sought to rival in medicine were universally execrated by the Irish people, and virtually abandoned by cabinets of all shades and colours, from the cabinet of WELLINGTON to that of MELBOURNE! Men with far less sagacity ought to have seen that the system of exclusion which was not maintainable in the church, in the corporations, or at the bar, could not be sustained in the medical profession. It was not prudence but sheer stupidity to stand between the ruin and its fall; but from the quarter to which the party have all along addressed themselves, they seemed to think that if they could meet the statements and arguments of *THE LANCET*, their case was safe. Yet even had this journal latterly been silent, the impetus it had already given to reform could not have been retarded much longer. Public opinion had become too strong an enemy for the junto to cope with. Were the profession in Ireland likely to be satisfied with less than was to be conceded to the profession in England and Scotland? Did they imagine, for instance, that the fact that not a single individual belonging to the faith professed by the bulk of the Irish nation, fills (as we believe) the office of surgeon or physician to any Irish County Infirmary, would not be considered as a gross anomaly and a scandalous grievance? Was it to be supposed that the people of Ireland would be content with an University, the by-laws of which declare that no Catholic shall ever hold in it the office of Professor? As well, indeed, might Dr. GRAVES and his party expect that the sturdy followers of Calvin in Scotland would allow the episcopalians in that

country to hold exclusive possession of all their universities and schools! And yet such is the proposition of the medical monopolists of Dublin!

But sooner or later will the inhabitants of Ireland either force open the existing institutions, or possess institutions of their own. They are intent upon this course. Their enemies force them to adopt it. We are perfectly aware of the kind of use that will be temporarily made of this announcement; nevertheless, the event cannot be retarded, however great may be the abuse cast upon *THE LANCET* by the monopolists. The question is not now, "Shall there be reform?" but "How far shall it be carried?" The spokesman, Dr. GRAVES, suspects this, or he would not have deviated from the old usage of treating public opinion with affected indifference, and admitted the necessity of reform, in his late "introductory" lecture at the *Meath Hospital*. The extent of reform will be discussed in the next harangue at that place.

In our present Number will be found the first part of an extremely interesting paper by Mr. EDMONDS, of Regent-square, on the influence which age n the population, and locality as regards divisions of the country, exercise over the mortality of various portions of the English population. The new and valuable materials—of unexampled variety and extent—on which Mr. EDMONDS has exercised his abilities and his great industry,—are but little, if at all, known to the public; and the devotion of so much time and attention to them as his papers evince, renders the community, for whose advantage they are designed, greatly his debtors. The chief of those materials consists of a Parliamentary return of the ages of nearly 4 millions (3,938,496) of deceased persons, and of more than 10 millions (10,530,671) of persons living, also distributed according to the terms of their age. These numbers have been divided into 100 portions, the sexes of the individuals enumerated being distinguished in each county in which the individuals are stated to reside; and also in each of six large towns. The "law of their mortality," or a careful dis-
number of these indi-
died at each distinct

number of persons who each lived to the same age, is the information which has been laboriously sought by Mr. EDMONDS, and ingeniously obtained by him from these materials.

In giving a place in our columns to the communication of Mr. EDMONDS, we are influenced by the impression, long ago entertained, that the subject is one of peculiar importance to the members of the medical profession. It can hardly fail to excite, indeed, a high degree of interest, local and general, amongst the people of this country; but to the medical community, especially, it affords an abundance of new and rich matter for reflection. The results themselves appear to us to be of high intrinsic value; but the exhibition of all the steps of the simple process by which they have been derived, may, perhaps, be considered of great permanent use as indications to the inexperienced in these matters, of the course which should be pursued in the investigation of the same, or of other similar materials. In medical statistics attention has hitherto been confined chiefly to the relative mortality resulting from different diseases, and to the number of deaths and recoveries which have occurred among a given number of persons attacked by disease. The duration of the attacks, and the ages of the patients, are indeed now deservedly becoming objects of great importance. But observations of this latter nature can supply no measure of the health of a population, so long as we continue ignorant of the number and ages of the persons living from whom the diseases are taken. In order to obtain an accurate measure of health, it is essential that the number and the ages both of the living and the dying should be observed. And that the number who are sick at each age should be distinguished.

It may serve, perhaps, to increase the attention of our professional brethren to the documents which we publish, when they are informed that very great secrecy is preserved on the facts which they develop, by the remainder of the very few persons besides Mr. EDMONDS, who possess any real knowledge on the subject.

space for the insertion of the proceedings which took place at the University

of London. The ministerial plan for founding a general university in the metropolis, is distinguished in many respects for its liberality; but the scheme will never receive our unqualified approval, unless the charter shall provide—after the institution is set in motion—for electing the future examiners by *concours*; nor, unless every candidate for the honours of the University shall be *admitted to examination*, simply on his furnishing proof of his having ever sustained a character of unimpeachable moral rectitude. The scheme in its present form will only add new strength and vigour to the odious, the infamous, certificate system. The letter, signed “A STUDENT,” in the present Number of *THE LANCET* (page 388) relating to this subject, merits general attention.

THE facts relating to the late disinterment of a body at Moulton, and the consequences resulting from the discovery of the proceeding, are not unknown to us. We only hope, for the credit of the profession, that any one of its members who may be at present involved in the charge connected with the disgraceful transaction, possesses the means of freeing himself with honour from the implication. The affair is undergoing legal investigation, and we shall therefore abstain from saying anything farther on the subject at present.

THE LATE DR. HAMILTON.

(From an Edinburgh Correspondent.)

DR. HAMILTON, the author of the valuable work on the treatment of diseases by purgatives, died on the 27th of October last, having arrived at the eighty-eighth year of his age, and enjoyed, during that long period of life, an uninterrupted course of good health.

There were many features in the life and character of this able physician which are worthy of notice. It may justly be said of him, that he constructed one of the best works on practical medicine which appeared during his day; and he was, at the same time, one of the best practitioners of the Scottish metropolis.

JAMES HAMILTON was the son of the Professor of Natural Philosophy of the University of Edinburgh. Having had an excellent preliminary education, he commenced

the study of medicine,—the school of Edinburgh having at that time acquired its highest reputation, its list of professors being adorned with the names of MONRO, CULLEN, BLACK, and GREGORY.

Finding an unconquerable difficulty in even witnessing operations of surgery, Dr. HAMILTON commenced practice as a physician; and although he always had the reputation of possessing good sense and a sound judgment, he was very little employed in private practice; and the greater portion of his time was devoted to the duties of the Royal Infirmary of the city. It was not until he had passed the fiftieth year of his age that he enjoyed any professional reputation. He had never devoted himself zealously to any pursuit connected with the science of his profession; and he was even defective in its rudiments, having, like his contemporary, the second GREGORY, no knowledge of practical anatomy; and possessing, consequently, no accurate knowledge of pathology.

At about this period of his life he came forward with his work on "Purgatives;" and never was any literary production more cordially received by the profession. The views which he inculcated therein were at once adopted by a great proportion of British practitioners. It passed through one edition after another, at once establishing the fame of the author as that of a first-rate practical physician.

At the same time that HAMILTON was directing the attention of the medical world to the administration of remedial measures in the treatment of fevers, and ascribing many diseases of the nervous system to the alimentary canal, ABERNETHY was employed in pointing out a variety of local ailments, all of which were symptomatic of a derangement of some portion of the digestive apparatus, and to these also ABERNETHY directed all his therapeutic means. Each observer was employed in exploring the same country, but they travelled in different roads. Both observers agreed on all practical points; they both agreed in the fact that almost every disease is modified by, if not actually originating in, a deranged state of the digestive canal; and whether it be the stomach itself, the liver, or the large intestines, it is those organs to which we must direct our chief remedies in all the diseases of the human body. In confirmation of this important truth, we have only to look at the habits of mankind in civilized life. The irregularity of their meals, and the multitudinous variety of their food, contrived purely to gratify sensual desires, must constantly disturb the functions of the stomach, while the moral excitement to which mankind is exposed, must, in like manner, constantly derange the operations of the liver. It was to this portion of the alimentary canal that ABERNETHY directed

particular attention in all his pathological investigations, whilst HAMILTON appears to have looked chiefly to the large intestine. To the congestion and accumulation of fecal matter in the colon, he attributed the chief affections of the nervous system, particularly chorea, but he considered that a vast number of symptoms of other diseases, originates in the condition of the alimentary canal. Both practitioners established their views by a reference to an immense body of facts, and their joint labours now form the groundwork of the practice of the ablest medical men in this country.

Much has been told, and truly told, of the absurdities into which these champions of the stomach occasionally fell, from the extravagant bias which their minds took on the subject, its diseases and remedies. To such an extent did Dr. HAMILTON carry some of his views, and so eager was he to inculcate the importance of examining the evacuated matters on all occasions, that in visiting his patients in the Royal Infirmary, he was in the habit of looking at the cloaca in every case. An old and waggish nurse who was employed in the Institution at one period, had no difficulty in providing an "evacuation" for the doctor's critical inspection, numerous as were the demands on her faculties of distinctiveness and arrangement. It was at once indeed a saving of trouble and a source of amusement to her to confuse the stools of the different patients, and then to present them to his notice indiscriminately. These deceptions, however, converted laughable errors into a useful conviction, on the minds of the numerous students who attended the Doctor's visits, that little was to be learned from the mere external characters of the evacuations from the alimentary canal.

As a private individual, Dr. HAMILTON was generally considered as a very primitive character. He was a perfectly upright and just man, but his generosity of disposition was not very conspicuous towards those who chanced to present claims on his benevolence. Though unmarried, he had the reputation of possessing a progeny. He was rather affected in his dress, continuing to wear a cocked-hat forty years after that form of heaver had been given up by every body except a few clergymen. He would not wear gloves even in the coldest days of which our northern climate can boast, and he always slept with the window of his room open. In personal appearance he was a little pleasant-looking body, and he generally contrived by his manner to make friends. His house being adjacent to that of Dr. HAMILTON junior, our well-known accoucheur, many amusing anecdotes are told of ladies making mistakes in the choice of their medical attendants. It was often proposed that the distinctions of "senior" and "junior" should be placed on the doors, some sym-

the houses, character of the favourite calling of each, in order that the victims of "Cupid" might not undergo an unmerited purgatory, by accidentally calling at the wrong house.

INTERCEPTED LETTER.

"DEAR SIR HENRY,—I always feel it to be an honour to receive a letter from you, and am ever proud to fulfil your commands. Your letter, most parts of which I read at a College meeting, was most gratifying. I am every day more convinced that you are not even yourself as well aware of your public as you are of your private professional value. We all look up to you, justly, as the chief pillar of our venerable institution; and we know that when you fall so must Pall Mall East. I rejoice in the amendment of your health and spirits, which at the last College meeting you attended we all observed had faded a good deal. Wiston Hall is a delightful spot, and I hope you will remain there until the close of November, in order that both your mind and body may be recruited. My solicitude to see you once more amongst us, prompts me to take the liberty of cautioning you not to make too free with your constitution, and expose yourself too much to the endearments of the fascinating circle in which you move, and have been so fondly caressed. I cannot help recalling to your memory the sage advice which you gave some years ago to the gallant Duke of WELLINGTON, and as you are much more advanced in years, the same precept may now be to you even more applicable. I am confident that by tender nursing and great command over your passions, your mind and body may yet last a few years. The aged are not less apt to become the victims of female society than youth, and if you at your time of life were to take to yourself a young wife, we should soon lose your valuable services. It is my high consideration of those services that prompts me to write to you on this delicate subject.

"I don't know that I have much news to tell you. All of us will join you heartily in keeping things at the College *in statu quo*, and we are every one confident that your ingenious and comprehensive mind will contrive a tub for the whole, and that you will easily manage to amuse these pettyfogging licentiates with another reform phantom. You have no one to fear, as all of us will be glad to keep you in the president's chair. There is in fact no other man in the profession high enough in rank and science to fill the same dignity and credit. The *think* are paralysed. MATON, certainly aspired, but he is a world. Had he been a we should not have

suppressed the facts respecting the indecorous part of his life. A married Fellow, with legitimate offspring, might have been something; but the least public suspicion of immoral habits, unfits any one to be an occupant of the President's chair. Such a person could never have overthrown a man with your high moral feelings. WARREN, whom you reasonably considered as an opponent, will soon leave this wicked world, for he is very very ill; so instead of fearing him, you may pray for him.

"I have done all I could to obtain information about the schools. The different lecture-rooms have been open some time, and I wish my statements respecting several of them could be more gratifying. But I must not deceive you. The medical pupils of the London University have increased prodigiously. Last year there were 300, but this year the number is not less than 500. The other schools have suffered a proportionate diminution, some of them having been hit most severely. St. Bartholomew's, notwithstanding all STANLEY's efforts, are 83 *minus*.

At the Borough hospitals they are making a convulsive struggle, but all the palm oil which King HARRISON can supply, does not seem to make the rusty wheels of Guy's go quicker. At St. Thomas's, however, the classes are a shade better. The reason is, I understand, that they are more liberal in their conduct to strangers. At Guy's their demeanour to visitors is quite ungentelemanly, and contrary to every rule observed at the other and more liberal recognised hospitals. They are machinating a quarterly journal of Reports. Such a thing is already advertised at St. Thomas's. But they are a dozen years too late. Had they been wide awake in 1823, they might have prevented the inconvenience of criticism with reporting. But they say that the unfortunate *Gazette* is read by so few that it does not answer the purpose of the hospital surgeons. These *pure* journals, however, must fail, as of course they will only contain successful cases, and will give none of the bungling practice. Nobody but a blockhead would publish an unsuccessful case.

"The Westminster School is as low as low can be. I conversed with a gentleman who went to hear one of the new-fashioned *clinicals*, and who, after waiting for three quarters of an hour, took his departure, because no other soul but the lecturer attended. GUTHRIE is sliding down rather fast, though he was never far up in the estimation of the competent judges. You will find a melancholy scene described in THE LANCET. All true! The College have kept the Charing Cross concern out of competition with their own hospitals, by refusing to recognise the practice. Our St. George's friends have met with the fate which you foresaw. The 7000*l.* sunk in brick and mortar, will never again be converted into currency. The two

contending parties have about shared equally in the pupils, each having from twenty-three to twenty-five. BRODIE, poor fellow, would not hearken to good advice and give up the opposition. LANE, who is as sharp as a needle, has certainly got the best shop, having spent upwards of 1500*l.* in putting the original school in order. The Middlesex must be considered as a failure. This I regret only on your nephew's account, for Sir Charles is a bitter enemy of things as they are, though, loud as he talks out of the College, we never hear of any of his efforts in doors to help the reformers. The University hospital has kidnapped every pupil in that quarter. By-the-by a new medicine, called *creosote*, is all the rage here. Have you ever heard of it?

"I saw TURPIN last night. He appeared low, and said the trade was *dull*, that he was *looking out* for patients, and that the old families who used to permit all their domestics to indulge in the *draught* system at the master's expense, now oblige them to go to dispensaries, or have their own doctors, which makes a serious difference in the Christmas bills of all the top-apothecaries. He says that no one now ever wants a pure physician, and that none of his patients will stand a *regular attendance* any longer. We are all fully sensible of the complete change which has taken place in the guinea trade, and every day see the necessity more and more of becoming, in reality, general practitioners.

"I have sent you per coach WARDROP's book on Blood-letting, which was published yesterday. I think it will please you. It is full of practical information, and contains what are to me many views which are quite original; but I should like to hear your opinion of the work. Favour me also by saying what number of copies I should order for our library, as it will be much called for, for it is a work not for a cursory perusal, but for attentive study and calm deliberation. There is one point in which you may obtain some useful information from it. I allude to the *quantity* of blood to be taken. I remember a lady, who was present at one of your visits, telling me of the happy effects produced by your nice discrimination of the requisite quantity to be removed in the case of the old Dowager Duchess of R*****. She said that after repeated most accurate examinations of the pulse, and of the alvine and urinary discharges, *a la Prout*, you prescribed the loss of *four ounces* of blood by cupping, and then departed; but on returning to your noble patient in two hours, and having first ascertained that the cupper had not arrived, you then, with your customary tact, expressed an unusual interest in the case, saying 'that your anxiety was more intense than it had ever been for any patient before,' and that 'after having contemplated, reviewed, and turned over again and again in your mind every particular of

her condition, you had come to the important determination that the *quantity* of blood to be removed should be only *three ounces and a half*.' I shall never forget the favourable impression which your conduct on that occasion made on all concerned; and for years after, the noble family of R***** could never hear your name mentioned without a tear of gratitude rolling down their cheeks.

"I am glad you are riding a quiet pony. What a frightful escape little BRODIE had in the Isle of Wight the other day! I trust you will have the kindness to let me know about the time that you will come to town, and say if I can do you any little kindness at Kensington. Do you think there will be a chance of getting up some meetings at the College this season? There are many difficulties which you alone can surmount, if surmountable. I remain, dear Sir Henry, ever your very humble and obliged servant,

"W. Mc. M.

"Half-moon Street, Oct. 1835."

LONDON MEDICAL SOCIETY.

Monday, Nov. 30, 1835.

DR. WHITING, President.

TREATMENT AND EFFECTS OF FRACTURES.

MR. BRYANT placed on the table a specimen of fracture of the femur, of which he gave the following history: A female, aged sixty-seven years, much addicted to drinking, occasioning considerable feebleness of constitution, was knocked down by a boy, when the left trochanter forcibly struck against a curb-stone. She was unable to rise, or bear the least weight on the limb. She was conveyed home and put to bed, and simply kept quiet. On the 27th of October, three days after the accident, she was brought to the infirmary, when the injured limb was found to be two inches shorter than the other. The foot was everted, and on rotating the limb, distinct crepitus could be heard and felt at the upper part of the thigh-bone. The woman was placed on a fractured bed, and the limb on a double-inclined plane, with splints and bandages to maintain the broken parts in apposition; and thus placed she appeared easy. On the following day she became extremely restless, pulled off the bandages and apparatus, and obstinately refused to have them re-adjusted. He (Mr. B.) then placed the limb on its outer side, with the knee bent on a pillow, insisting on perfect rest being kept. She remained more comfortable, but became even more feeble, although a supply of wine, which she had been a long time refused, was allowed her. The patient did not get

pulse rapid and feeble, and the tongue dry and brown. The symptoms continued increasing up to Saturday, 28th November, when she died. On examination, a fracture was found through the trochanter; the neck of the femur was driven into the cancellated structure, and the trochanter minor was broken off. The fracture was external to the capsular ligament, but no attempt at union had occurred. Cases, however, of fracture of this description were described by Sir Astley Cooper, where union did follow. His (Mr. Bryant's) object in bringing this case before the Society was to engage its attention on the treatment of such injuries, which he thought was a very desirable object, especially at the present time, as an excellent paper had been lately published in *THE LANCET*, by a Mr. Radley, who had advanced, very ably and strongly, the treatment of fractures without splints. The plan recommended by Mr. Radley appeared to have been so successful with Mr. R., that it could not be otherwise than worthy the attention of every medical society. Two other specimens of fracture, on the table, were taken, the one from an old man aged sixty years, and the other from a woman aged sixty-three, the injuries arising, no doubt, from the extreme fragility of the bones at their advanced ages; and he (Mr. B.) was very sceptical whether the practice of confining the patients on the back, with the limb extended, was a good one. In fact he was led to consider that great advantages would result from the surgical treatment recommended by Mr. Radley. He (Mr. Bryant) did not consider that any benefit would have ensued in the present case if mechanical contrivances had been adopted; and in such cases he regarded the position on the side, with the knee bent, resting on a pillow, the most likely to answer the object of the surgeon. The Society's time, he believed, would not be ill-spent in giving this important subject an attentive consideration. In the case of the female first mentioned to-night, he believed that the accident had but little to do with her death; for but very slight inconvenience arose from the fracture. He, perhaps, might account for the fatal event correctly, by asserting it to be the woman's having become habituated to the use of ardent spirits, which having been in the first instance withdrawn, low fever ensued, which, in its turn, by degrees, occasioned the feebleness under which she sank.

Mr. JONES was persuaded that patients having received severe injuries, died, in innumerable instances, from a peculiar kind of slow fever that succeeded, without disclosing any structural change. Irritation, he regarded as a frequent cause of fracture, for instance. He was disposed to think, that the death of Mr. Bryant's patient was not

referable to the injury, but to the shock which the whole nervous system had sustained. He had seen many persons die from falls which had produced no fractures, in the course of a very few days.

Mr. DENDY pronounced Mr. Radley's plan to be no plan at all, for it permitted the patients to do as they pleased, when, if there were any disposition to displacement of the disunited parts, the treatment without splints would not succeed. In Mr. Bryant's case little could be done, but he (Mr. D.) would have added a pelvic strap, to keep the pelvis fixed.

Mr. CLIFTON considered the principal source of irritation in very old people, to depend on the confinement and restraint to which they were subjected after the receipt of an injury.

Mr. PILCHER attributed the development of the irritation, rather to the confinement than to the abstraction of the stimulants, the former leading to an interruption of the functions of the body, and finally to a disorganization of the viscera.

Dr. JOHNSON maintained that the irritation or mischief resulted from the shock which the constitution had received.

An animated discourse ensued, terminating, however, in each member regarding his own theory as most feasible, in accounting for the phenomena occasioning death in such cases, and the Society soon afterwards adjourned.

OUR REPORTER remarks on the note of Mr. Hooper in the last *LANCET*, "that he did not anywhere state in his report, that Mr. H. had said that, 'the exostosis on the tibia of the patient well illustrated the proposition laid down by Mr. Abernethy;' but, rather, what Mr. H. himself states in his note (page 349), viz., that cancer will invade every structure of the body. Although the word exostosis was perfectly separate from the sentence, still it had reference to it; for, as stated in the report, not only soft parts were destroyed by cancer, but bony parts also."

WESTMINSTER MEDICAL SOCIETY.

Saturday, Nov. 28, 1835.

Mr. RICHARD QUAIN in the Chair.

DEATH FROM TAKING MORISON'S PILLS.

Dr. JOHNSON, in answer to a call from Dr. Granville, detailed the post-mortem appearances of Mrs. Sarah Porter, aged 39 years, who died from effects caused by taking Morison's pills. The particulars of the case were given in our report from the London Medical Society, Nov. 33, the day on which she died. The abdomen was rather tumid and distended; peritoneum healthy;

stomach inflamed, presenting slight abrasions of the mucous coat; no changes in the duodenum; jejunum and ileum twisted in different parts one with the other, and the morbid parts had assumed the colour of dark mahogany, with distinct demarcations of healthy surfaces; the vessels were injected, and from their capillary extremities blood was extravasated; there were no traces of ulceration, the mucous surface being simply abraded. The parietes of the heart were rather thicker than usual, probably the commencement of an hypertrophied condition. The bloodvessels of the brain were congested throughout, but there were no other morbid changes affecting the substance of that organ. In answer to a question whether the pills had ceased to produce any action some time prior to death, Dr. Johnson said that the medical gentleman in attendance, and the friends of the deceased, had informed him, that ten days prior to her death, she was recommended to give to one of her children, who was troubled with palpitation of the heart, some of "Morison's Pills;" she complied, but the child got worse. Presently the mother had pain in the head, and she also took them, in doses such as we have before described, producing, shortly after, distressing vomiting and violent purging; and her adviser remarked, that the more actively they operated, the greater number of pills it was necessary to take! An increase in the violence of the symptoms necessarily followed. The friends finding her becoming rapidly worse, sent for Mr. B—, a medical practitioner, who found her comatose, in which state she remained up to the period of her death, four days after commencing to take the pills. The last day or two prior to the fatal event, the bowels had ceased to act, and at the post-mortem examination they were simply distended with air. He (Dr. J.) came to the conclusion that death was occasioned by the pills, from the fact that some portions of the tube were highly diseased, whilst other portions were perfectly healthy; and where the lodgement of the irritating substances had taken place, there the changes were evident, and the contractions appeared as if tied with a piece of silk, while there no morbid adhesions had supervened; these contractions, when found in the healthy portions of the canal, were a positive evidence of their having been produced by the direct application of an irritating substance. But he did not wish it to be understood that he believed that other powerful pills, taken in the same enormous quantities, would not have occasioned the same result. (The virtues of this quack medicine, however, are said to reside in large doses.) The affection of the head was attributed to the large doses of Ext. Conii.*

* We believe the manufacturer, in order to baffle the analyst, changes his formula (with the exception

which the pills, by analysis, were found to contain.

Mr. VERRAL said he had been requested to attend an old patient, who, he was convinced, had also met with his death from the same cause; and in whom the pills and other aperients, towards the close, ceased to produce any action. After death an immense mass of the pills and of oil was found wedged in the intestinal canal, in so putrid a state, and emitting so powerful an effluvia, that the like he never before encountered.

MEDICAL MAGNETISM.

Dr. JOHNSON, in a brief address, re-introduced this subject, but it occupied attention only for a short time, the conversation consisting of a few questions that were put to Dr. Schmidt. The discussion of the previous night, Dr. Johnson said, proved to the Society that medical men were not the only class of philosophers who differed. As much variance of opinion prevailed to-night as on the last evening of discussion.

Dr. RITCHIE denied that the magnet, by itself, could produce any therapeutic effects.

Dr. SCHMIDT maintained that it could, if the poles were placed according to his arrangement.

Dr. RITCHIE thought it quite a joke that Dr. Schmidt should know how to manufacture magnets more powerfully, and place them more remedially, than other persons.

Dr. EVRS replied, that a gentleman had offered to Messrs. Watkins and Hill, of Charing Cross, 100 guineas if they would produce magnets having the like power.* They tried, but at last were compelled to acknowledge their incompetency; and he would now propose that Dr. Ritchie and Dr. Schmidt should each take a certain number of pieces of iron, and try who could produce the most powerful magnets.

Dr. SCHMIDT offered any medical gentleman who doubted his competency to perform what he had described, or who believed that the magnet could not produce physiological effects on the human body, to bring to his (Dr. S.'s) residence, any poor and sick patients on whom magnetism might be tried, the visitor judging for himself of the results, for he had no secrets to conceal. He had abstained from quoting cases cured with the magnet within the last six years. He would, however, briefly state that he knew a lady, aged 22 years, afflicted with amaurosis for several years, and who, during the last eighteen months, was completely blind,

of the ingredients that give to his pills their powerful drastic aperient quality), as it best pleases his fancy, when preparing the means of deception, for some analyses furnish the like product.—*Hep.*

* We take this opportunity

Dr. Schmidt withholds relative to his mode of magnets?—Ed. L.

who was seen by several eminent physicians, without benefit, but in whom the magnet produced a speedy and perfect cure. It could avail nothing to detail cases within these walls, unless authenticated by the residence of the patients themselves. Many remedies there certainly were in the pharmacopœia, but the profession, nevertheless, was not overstocked with remedies.

Mr. HALE THOMPSON said he was authorized to offer to Dr. Schmidt the use of the Ophthalmic Institution, where he might select as many cases of amaurosis as he thought advisable, and in order that the magnet might have a fair trial, the sole management of the selected cases should be entrusted to his care, and he (Mr. T.) would give to the Society an impartial statement of the results.

The offer was accepted, but not so willingly, apparently, as to prevent Mr. KING from believing that a reluctance existed on his part of Dr. Schmidt so to test the efficacy of the magnet. Mr. KING considered that more effect would be derived from electricity, though whether the magnetic fluid suffered from the electric he was not aware.

Dr. SCHMIDT said he had found injurious results to arise from the application of electricity in the treatment of diseases, and moreover, he had not so great a control over the electric as the magnetic influence.

Dr. JOHNSON advised Dr. Schmidt to accept the offer to make experiments at the public institutions, but to be careful in the selection of patients, especially those affected with amaurosis, for it was impossible, he considered, that any remedy could accomplish a cure when the cause arose from organic changes.—On the whole, the Society seemed to form a more favourable opinion of magnetism this evening, the interest in the subject being heightened when it was announced that Dr. Faraday had purchased one of Dr. Schmidt's magnets (which Dr. S. considered as a proof that his magnets were very superior) and examined his experiments, remarking that his views were new, on some points, and no doubt would lead to important results, he (Dr. F.) stating that he should more fully investigate the subject. The adjournment of the Society then took place.

MEDICAL CONTRACTS IN THE NEW UNIONS.

LETTER FROM MR. CEELEY OF AYLESBURY,

To the Editor of THE LANCET.

I have never been among the number who have derived the least benefit, and any hope, from the Poor-Law Commissioners

to the Kent deputation:—"That the guardians of the poor of the respective parishes should not be prevented entering into as many contracts with medical men as they pleased,* because, in the first place, in the rules and regulations originally issued for boards of guardians by the commissioners, a clause exists, relating to medical relief, permissive of such authority,—a clause which, in an official communication on the subject, dated June 20th last (now before me), their secretary states, "he is instructed to declare, empowers guardians to exercise an *entire discretion* with regard to the medical appointments." In the second place, experience has taught me to entertain no very exalted opinion of the discretion of such bodies in general on such a subject. In the third place, I am unwilling to respect the declarations, and unable to appreciate the authority, of a central triumvirate which, though incessantly disclaiming all interference in the medical arrangements, and for ever alluding to the grant of these discretionary powers, at the same time permits most of its itinerant assistants to be actively and relentlessly engaged in prejudicing, insulting, and degrading the medical profession, often *prompting* guardians to the execution, and *always* supporting them in the inflection, of the most flagrant injustice on numbers of its worthiest members.

For these reasons, also, I could not participate in the surprise expressed by you, in a recent Number of THE LANCET, at the proceedings relative to medical contracts, still manifested by the guardians of several unions, much less can I concur in the correctness of your strictures of the 21st inst. on this subject.

I could relate many instances in different counties, previous to the Kent deputation, where guardians, uninfluenced by assistant commissioners, have exercised this discretionary power with humanity to the poor and justice to the medical profession. I could also mention a multitude of instances, both before and since that event, where, in spite of the above recited discretionary clause, the secretary's authorized explanation, and the reiterated official assurances in the House of Commons, assistant commissioners have most illiberally and unjustly interfered in these matters, either dissuading them from the pursuit of an enlightened and judicious course, pandering to their parsimony, or ministering to their meanness. Boards of guardians, in general, need not such *assistants*; and it is equally true, that had those bodies been left to their own feelings, knowledge, and discernment, infinitely less evil, and much less injustice, would have been perpetrated in the medical arrangements.

* Vide LANCET, No. 927, p. 747.

In the Wycombe Union, formed some months since, the guardians refused to admit of medical districts, though urged to it by Mr. Sub-Commissioner Gilbert. He, however, succeeded in persuading the Board, after having unanimously agreed to the adoption of a low scale of graduated payment, proposed by a medical man of acknowledged talent, experience, and liberality, to abandon their design, and force the medical men, by modern threats, to accept a shamefully inadequate stipend.

This functionary, doubtless, in laudable rivalry with his associates, declared publicly and privately, "that the medical men of Buckinghamshire had given him so much trouble that, on all occasions, he would urge the guardians to procure medical officers from London"—"that although they had caused him most trouble, yet he could always subdue them by introducing very clever young men from Somerset House, where there was always a long list of them in the possession of the commissioners."

The Aylesbury Union comprises forty parishes, and contains a population of more than 22,000, with districts most preposterously and perniciously arranged in reference to the medical duties, and is it not less than twenty miles in extent in one direction. During the formation of this union, that sagacious gentleman Mr. Gilbert gravely inquired "whether one medical officer would not suffice for the entire Union."

When the Union was formed, in September last, he took an active part in dividing it into four arbitrary districts for the relieving and medical officers, and suggested terms for the latter to which none of the resident practitioners could accede. The Union was disposed of to three individuals; two from London, one having two districts, who are engaged to discharge the medico-parochial duties lately performed by sixteen! Whether the medical men in Devonshire have proved more compliant than those of Buckinghamshire, or whether this gentleman *there* continues his pragmatical proceedings, our brethren in the South, I dare say, can inform you.

In Hertfordshire, after a contract had been ratified, the assistant commissioner, Mr. Adey, refused to sanction it till 7s. 6d. was substituted for 10s. 6d. for midwifery, in and out of town. In Bedfordshire, guardians have been officially informed that the *commissioners* would not allow more than 7s. 6d. for this important item. This gentleman has publicly declared, "that, notwithstanding medical men now complain of inadequate parochial remuneration, they will receive much less next year."

In the Thame Union, where the medical appointments have been made within this last month, and where the *highest* tenders were accepted, the Assistant Commissioner, Mr. Gimson, and the Central Board, inter-

fered. The former offered a London medical man at a lower rate, at the same time declaring that the election just made would not be confirmed. The latter proposed a sum scarcely equal to two-thirds of that claimed by the successful candidates.

The guardians, however, after much discussion, would not accede to this, but ultimately were induced to propose a considerable reduction of the original terms. Contracts, on these abated terms, were then ratified by the guardians, for *twelve months*. Within these few days, however, the Central Board—the Poor-Law Commissioners—have signified to them in writing, "that, under the circumstances, they will allow the medical appointments to continue only *until the end of the parochial year*: at the same time they consider the remuneration proposed too high, and such as they will not feel justified in sanctioning in future."

If further evidence could be required to show the spirit actuating the Central Board towards the medical profession, and to declare the hopes we may entertain from that quarter, surely their last Report to Lord John Russell will furnish abundance. That report can be proved to be no less replete with unwarrantable aspersions and unfounded imputations, than distinguished for the arrogant folly and the ignorant credulity of its subordinate concoctors. It may, in its characteristics, stand unrivalled; but I am happy to say it will not remain unanswered. I do hope, as you suggest, that it will at once engage the serious attention of the profession in general; and that, since his Lordship has the bane, he may also have the antidote.

By extensive union, cordial co-operation, and an appeal to the Legislature, supported by authentic facts, existing in abundance, I cannot doubt that the honour and respectability of our profession will be best vindicated and most successfully maintained.

I am, Sir, your obedient servant,

ROBERT CECILY.

Aylesbury, Nov. 30, 1835.

METROPOLITAN DEGREES IN MEDICINE.

To the Editor of THE LANCET.

SIR,—I perceive by the daily papers, that it is the intention of the Government to "incorporate by charter certain persons eminent in literature and science, as the 'University of London,' with power, after examination, to confer degrees in arts, law, and medicine." It is also stated, that candidates for degrees must produce *proofs of having gone through a course of study*, either at the "

* Vide LANCET, No.

at the institution now denominated "The London University."

Now, Sir, this does appear to me to be neither more nor less than a continuance of the old system, and to imply that the examination for degrees, at the new "University of London," will be as useless as that process has hitherto been in other quarters. If it be not a perpetration of the old scheme under a new name, why is it necessary that a regular course of study should be "gone through" at any institution whatever? The circumstance that a candidate has passed a certain number of years in professedly educating himself anywhere, is no proof of the ability or attainments of the professedly educated individual; and it is a fact which cannot be disputed, that many persons have attained degrees, in our two great universities, without presenting any solid claim to the possession of those marks of distinction. So that it would seem already, that neither certificates of having studied, nor the fact of having passed an examination under the influence of the old system, is any guarantee of qualification to hold a diploma.

But suppose we admit that the examination will prove so good, that none but competent men can pass the proposed examination. What then is the use of certificates of "courses of study?" Why should only those who can afford to obtain their knowledge at a university, be qualified to become candidates? The adoption of such a system necessarily excludes all but the comparatively rich. The want of means must prevent many able young men from pursuing their studies in an English university, but who, in the retirement of a private study, would attain a degree of knowledge which is far beyond that possessed by the majority of those who go through "courses of study," and obtain degrees. It does not matter *how* knowledge is obtained, — whether in the solitude of Welsh mountains, within the walls of a university, or amidst the din of a metropolis, — whether in Wales, France, or England. If the knowledge be but obtained, its possessor is equally worthy.

But, perhaps a fear is entertained by certain parties, that such an arrangement would increase the labour of an examination, because much which ought to be proved at an examination, is now taken for granted, or would be so, under the "course-of-study" system. But, even were more labour required, such labour would not be lost, for the worthiness of the possessor of degrees would thus be ensured. We might then look upon a degree as a thing of value, — as the evidence of a fair and adequate test of attainments, — satisfied that whoever possessed one, would first have proved before the public, and renowned that he had de-

throughout exerted yourself to obtain a pure mode of government in our metropolitan collegiate institutions. I have, therefore, no doubt that you will insert these remarks in *THE LANCET*, and give the liberal side of the question all the support in your power. I am, Sir, yours truly,

A STUDENT.

London, Nov. 28, 1835.

MEDICAL REFORM IN IRELAND.

To the Editor of *THE LANCET*.

SIR, — In the last Number of your truly independent journal you have been pleased to notice and comment on a lecture lately delivered by me in the Peter-street School of Anatomy, Medicine, and Surgery, in which I introduced the important subject of medical reform. Judging from certain passages in the commentary I am induced to think that your reporter must have either mistaken my meaning, or otherwise (unintentionally no doubt) fallen into error in reference to some points connected with the discussion of this very interesting topic. In order to prevent misconception or misunderstanding in the minds of the readers of *THE LANCET*, may I beg you will give insertion to the following explanatory observations in your next Number? In the commentary the following passage is to be found: —

"So far, therefore, as the act of divesting the theme of its imaginary horrors, and of calling general attention, by personal appeal, to its examination, is a meritorious one, we cordially concur in the favourable estimate which we hear was formed by his auditors of the manner in which Mr. Ellis discharged the duty he had undertaken. But if our report of the lecture be correct, we cannot state that we think his enumeration of medical abuses was so comprehensive as it should have been in a discourse professionally devoted to their discussion. Some of these omissions are, indeed, so remarkable that we mean to notice them. In our experience every sound reformer has always looked upon the system of compulsory apprenticeships as one of the baneful usages of the surgical profession in Ireland. They have also ever thought the scale of fees to sickness hospital practice most oppressively and iniquitously unjust. Yet, upon these two important items in the catalogue of medical abuse, no opinion was given in the oration of Mr. Ellis. In these omissions, which we presume were accidental, he was neither just to himself, nor to the question which he designed to advocate, and he ought to have foreseen that the absence of condemnation of such glaring and noxious features in the picture of medical economy in these countries, might, with seeming justice, expose him to the unworthy suspicion that he was performing the play of Hamlet, 'with the part of Hamlet left out by special desire.'"

I consider the first sentence of this passage complimentary to a degree quite beyond my humble deserts; for, in my opinion little praise is due to a person for the mere discharge of what he conceives to be a duty which he owes to the public, the profession, and the situation which he may chance to occupy in society. If I were so fortunate as to obtain the approbation of my hearers

distinguished yourself in the medical reform, and have

on the occasion alluded to, my success is much more attributable to the "good cause" in which I was embarked, than to the ability of its talentless, though zealous, advocate. In the second sentence you candidly assert that "if *your* report of the lecture be correct," that you do not think that my "enumeration of medical abuses was so extensive as it should have been, in a discourse professedly devoted to their discussion." Here, in the first instance, you have been led into a mistake; for, although the advertisement to which you make allusion in the first part of your commentary did announce that the "important subject of medical reform" would be *introduced*, it did not state that the lecture would be *exclusively* "devoted" to the discussion of medical abuses; and, indeed, even if it were, *your* reporter ought to know that "the catalogue" is much too long to be elaborately discussed within the short period usually allotted to a lecture. The fact is simply this; the lecture in question occupied an hour and three-quarters in its delivery; the first half-hour was spent in general observations on the subject of medical education, and the remainder of the time was devoted to the exposure of some of the most glaring of the countless and multifarious abuses with which the medical corporations, and the hospital and dispensary establishments of these countries, abound. You will, therefore, I trust, give me credit for veracity when I assure you, that if I have failed to satisfy your reporter in the length of the discussion and in the character of the numerous topics it involved, the omissions complained of, *if real*, could be more fairly attributed to want of time than any disposition on my part of suppressing truth "by special desire," as delicately insinuated by the commentator on "the report." He states that some of these omissions are indeed so remarkable that he means to notice them, and then goes on to say, that in his "experience every sound reformer has always looked upon the system of *compulsory** apprenticeship as one of the most baneful usages of the surgical profession in Ireland." Now, Sir, I am quite at a loss to understand what the writer of this passage means; there is no such thing, nor has there been since 1828, as "a system of *compulsory* apprenticeships in the surgical profession in Ireland." Am I, therefore, to be censured because I did not betake myself to the tomb of a defunct monopoly, and exhume therefrom, as a topic for discussion, the ashes of an abuse which has had no material existence for the last seven years, when I found myriads of living and substantial ones obtruding themselves on my attention, and loudly demanding exposure? Would time

permit, or common sense tolerate, such a line of procedure?

On the subject of hospital fees I believe I did not make any direct or specific observations; however, by a reference to the report, "if it be correct," it may be inferred that I am favourable to their *total* abolition, *provided* the medical officers be *otherwise* remunerated for their attendance, and the time and trouble bestowed in giving clinical instruction to the pupils. When speaking of the French system of medical education I expressed an opinion favourable to it, and explained at the same time that there were no fees demanded from students for the privilege of witnessing hospital practice in Paris. I may here perhaps be permitted to add as an item in my defence against the insinuated charge of wilful omissions, that the pupil-money received at the Jervis-street hospital, to which I belong, is applied to the support of the institution, whilst the surgeons are left unrequited, not only for their professional attendance on the patients, but likewise for the time and trouble consumed in imparting clinical instruction to the pupils.

The last charge advanced is contained in the following passage. "In speaking for example, of hospital appointments derived by 'purchase' and 'descent,' our report of his lecture describes him to have said that the persons who are concerned in this infamous traffic and practice are warranted in their proceedings. Making every allowance for the intention of condemning the crime and saving the transgressor, which we consider to have been the object of Mr. Ellis in this nice discrimination, it is unquestionably true that no man has a right to enter into a compact which will be of detriment to the public welfare." Here again the reporter must have mistaken my meaning, if he supposed that I meant either to justify or defend in an *unqualified* manner, either the actors or the means by which the appointments alluded to are generally effected. However, when I express myself thus, I by no means admit the correctness of the assumed premises that all such appointments must necessarily "be productive of detriment to the public welfare." For instance, suppose a case in which an hospital surgeon, or physician, has, either from excess of occupation, indisposition, indifference, or any other cause, performed *no* part of the duties of his station, with the single exception of receiving annually *his* dividend of the pupil fund; yet he will not resign, and, unfortunately, he has enough of friends on the *managing* committee to save him from *compulsion*. Now, would it not be more conducive to the interests and the objects of the institution, and "the public welfare," if a person could be *induced* to resign, or be *compelled*, under the sign, and in this way,

* This was an error of the press. The word accidentally obtained its place in the page, after the mark of erasure was affixed against it in the proof. — E. L.

petent successor who would feel both a pleasure and a pride in faithfully discharging the important offices which his sense of duty would impel him to fulfil? This is by no means an extravagantly conceived, or imaginary exemplification, either of contempt of obligations seriously imposed, or of human leprocity, as exemplified in our medical corps. I could, in support of my argument, name, if necessary, an individual who was practically illustrated by his conduct for the last twenty years the truth of the position I here lay down; and I could likewise mention three or four instances of *salutary exchanges* which have taken place in hospital appointments, although they were effected chiefly by *private arrangement*. Give me leave to add that, in my opinion, the man who obstinately perseveres in *monopolizing* an important medical situation, and will, in the dog-and-the-manger fashion, neither do the duty, nor resign, but takes advantage of his spurious interest and vitiated influence with a corrupt committee, is much more culpable than a person who would vacate even for a pecuniary consideration. As long as the present system is permitted to continue in operation, and human nature remains what it is, *moralize* as we may, *nepotism*, *patronage*, and *money*, will exert a preponderating influence in determining medical appointments, both in Great Britain and Ireland, and the "infamous traffic and practice" will go uninterruptedly on, until restrained by the powerful arm of legislative enactment. It appears to me that the adoption of the principle of the concours in reference to hospital appointments in these countries would be the most efficacious method of putting a stop to the "flagrant abuse" complained of; and that it is only by rendering the commission of "the crime" impracticable, that "the weapon" can be effectively wrested from "the aggressor." This is the opinion I expressed, and the doctrine which I endeavoured to promulgate, when delivering my unimportant sentiments on the important subject of *MEDICAL REFORM*.

I have the honour to remain, with great respect, your obedient humble servant,

ANDREW ELLIS.

47, William-street, Dublin,

DELIRIUM WITH TREMOUR.

To the Editor.—SIR,—Your correspondent respecting *Delirium Tremens*, in your last number,—and who need not have appeared anonymously in the matter,—is certainly correct in supposing that I have inadvertently over-estimated the importance of Dr. Elliotson's lecture. His lecture was published on the 10th inst., and that my article on the subject appeared in your hands at the time; this has since been afterwards added

in the proof. Upon referring to my article, I observe, that the names I have suggested among the synonyms are, "*Idiopathic Delirium*;" "*Delirium Tremefaciens*;" and I have accordingly placed the word "*author*" after them. As to the pathological doctrine and division I have claimed, I remain of the same opinion as before. Upon looking into my friend Dr. Elliotson's able lecture, I found that part of it which is devoted to delirium tremens methodically arranged into "*Symptoms*," "*Causes*," "*Diagnosis*," and "*Treatment*;" but I could not find the distinctions in question under either of the heads "*Symptoms*" and "*Diagnosis*," where I expected to find them; and it was not until I had arrived nearly at the conclusion of the "*Treatment*;" that I found the subject adverted to, and there only in an incidental manner. I may take occasion to state, that the first case which directed my attention to the distinction in question occurred in a dispensary patient in 1821; and that, about ten years ago, I attended, within a few months of each other, three cases of the disease, with Mr. Houston, of Lisson Grove, a gentleman well known to Dr. Elliotson and myself for his extensive literary and scientific acquisitions, as well as for his experience; and one of these cases presented the inflammatory character, and occurred under the circumstances which I have detailed at length. I do not dispute that the distinction was made about the same time by Dr. Elliotson and myself; but that I have been indebted to his lecture I unequivocally deny. Whoever will first read Dr. E.'s lecture, and immediately afterwards my articles on "*Delirium*," and "*Delirium with tremor*," will find internal evidence of my originality. If I may judge from my feelings and habits, I should infer that, in glancing—for I can do no more in many instances, even where I make references—over this lecture, I perceived nothing which particularly struck me, otherwise I would have taken further notice of it; and that the topic in question should have escaped me is not surprising, when the head under which it was noticed, both briefly and incidentally, is taken into account.

I am, Sir, your obedient servant,

JAMES COPLAND.

Bulstrode-street, Nov. 30, 1835.

CORRESPONDENTS.

WE have received another communication from Mr. ROGERS, in reply to the letter of Mr. G. Bury, relative to the proceedings at the late inquest at Farnham. We think we shall best consult the ends of justice by excluding from our columns any further remarks on the subjects in dispute until we have obtained an official copy of the depositions taken at the inquest. It is not necessary to say one word in justification of the conduct of Mr. ROGERS. He has manfully stepped forward to protect the character of an innocent man; and in doing so, will obtain the approbation of every just intelligent member of society.

WE have not space for the letter signed C., but we give insertion, for the satisfaction of the writer and the information of his friends, to the following passage, which is strictly applicable to the case, from the excellent work of Jervis on the office and duty of Coroners. Nothing can be more evident than the fact that no inquest should have been held on the occasion in question:—

"The dying suddenly is not to be understood as relating to a fever, an apoplexy, or other visitation of God, and Coroners ought not in such cases, to obtrude themselves

into private families for the purpose of instituting inquiry, but should wait until they are sent for by the peace officers of the place, to whom it is the duty of those in whose houses violent or unnatural deaths occur, to make immediate communication, whilst the body is fresh, and, if possible, whilst it remains in the same situation as when the person died. But, under whatever circumstances, this authority must be exercised within the limits of a sound discretion; and unless there be a reasonable ground of suspicion that the party came to his death by violent and unnatural means, there is no occasion, except in the case of a person dying in jail, for the interference of the Coroner. In fact, Coroners have, on several occasions, been censured by the Court of King's Bench for holding repeated and unnecessary inquests, for the sake of enhancing their fees, where there was no reasonable probability that the deaths occurred from violence or unnatural causes."

A correspondent is anxious to throw out a suggestion, "That any new Board of Metropolitan University Examiners should have the power of conferring degrees in surgery, as at Glasgow and on the Continent, the candidates having bestowed on them, according to their acquirements, degrees of C.B., C.M., and C.D."

A Constant Reader.—If the party practise as an apothecary, he is liable to prosecution.

A Shareholder will see that the scheme of compulsory residence which his propositions involve, cannot obtain from us any support as a part of a code of regulations for conferring degrees in surgery.

We have not room this week for our reports from the Phenologist, the Medico-Chirurgical, and the Western Medical Societies, and many communications from correspondents, though we have this week added eight pages to the next Number of the Journal, etc. unavoidable omissions.

An account of the proceedings of the Medical Association of Tonbridge, which has been kindly forwarded to us by Mr. W. May, shall appear in the next Number of THE LANCET.

Philo-Justitia, and the letter of our correspondent from Brighton, next week.

Mr. SCHLOSS has published a good lithographic sketch of the celebrated Professor TIEDEMANN. The likeness, taken while the Professor was lately in London, by a Mr. S. Laurence, is very faithful. It reminds us of the portraits of Abernethy, but the face has a more sedate and intellectual expression. A very cunning cast of countenance was given by most of the painters to the English surgeon.

THE BRITISH MEDICAL ALMANACK for 1836 has just been published by Messrs. Sherwood. We have not room this week to say more on the subject of this annual, than that it is a work of infinite labour, and contains a vast fund of matter expressly interesting and useful to the members of the medical profession.

LECTURES

ON

DISEASES OF THE BRAIN AND NERVOUS SYSTEM,

NOW IN THE COURSE OF DELIVERY IN THE UNIVERSITY OF PARIS.

By M. ANDRAL,

Physician in Chief to the Hôpital de la Pitié, and Professor, and Lecturer on the Principles and Practice of Medicine, in the Faculté de Médecine of Paris.

LECTURES II. & III.

CONGESTION OF THE BRAIN.

GENTLEMEN,—In our last lecture I insisted at some length on the various difficulties which present themselves in the study of diseases of the nervous system, and endeavoured to explain the nature of those obstacles, at the same time pointing out some of the principal means by which they may be overcome. I shall now enter at once into the history of diseases of the central nervous system, by which we mean the brain and spinal marrow. Let us commence with lesions of the circulation, and, first, with hyperemia, the most simple form. After congestion, we shall take up the history of inflammation, then pass to anemia, and, finally, terminate this portion of our subject with hemorrhages of the brain and spinal marrow. Such is the method we propose to adopt. As for inflammation of the meninges, it occupies our attention when we describe the diseases of serous membranes in general, we shall not, therefore, refer to it during the present course.

Anatomical Forms of Cerebral Hyperemia.

Hyperemia of the substance of the brain, or, in other words, cerebral congestion, is a very common disease of the nervous system, and it presents the different forms under which it is known. It itself is numerous and varied, and may be general, occupying the whole of the cerebral substance; or it may be limited to a certain cir-

cumscribed portion of the brain. It may, again, attack simultaneously both hemispheres, or it may be confined to only one, and this latter circumstance is not of very rare occurrence. When thus limited, the hyperemia very often gives rise to symptoms closely resembling those of cerebral hemorrhage, from which it is almost impossible to distinguish it. In some cases the congestion is bounded to a single fraction of the hemisphere, and, finally, cases have been observed where the injection was confined to one of the cerebral lobules. Thus you see, gentlemen, the phenomenon which now occupies our attention may follow exactly the anatomical divisions of the organ that is the seat of the malady. This is a curious circumstance, and not confined to the brain alone. How frequently do we observe the same thing in the lungs, where the inflammation sometimes occupies both sides of the chest, sometimes attacks but a single lung, at other times affects one lobe, or, finally, as in the lobular pneumonia of children, may be confined to the ramifications of a single bronchus! These are not the only divisions of cerebral hyperemia; it may attack more particularly either the gray or the white substance, the congestion existing at some point of the surface of the brain, or being situated more or less deeply towards the centre of the organ. Hyperemia of the nervous centres may also be found in other parts of the brain: thus, it is not rare to observe a greater or less congestion of the pons varolii, or of the cerebellum; and in this latter organ, as in the cerebrum, the congestion may occupy the middle, or either of the lateral lobes. Finally, the spinal marrow alone may be affected, either generally, or at any one point, from the protuberance to its termination in the cauda equina.

Here let us first examine briefly the anatomical characters of cerebral hyperemia; they are, in most cases, sufficiently well marked. The coloration of the cerebral substance in cases of hyperemia is of two kinds, presenting,—1st, either a uniform redness—or, 2nd, a reddish colour from a number of small red points that occupy its substance. These two forms again differ, as they may occupy the white

or the gray cerebral matter. The spotted redness (*rougeur pointillée*) is most remarkable in the medullary portion of the brain, and when the latter is divided into thin slices, the surface exhibits an immense number of small bleeding points, as if it were scattered over with a quantity of fine red sand. These points are nothing but the orifices of so many divided vessels abnormally injected, and the peculiar appearance has given rise to the term "sandy injection," adopted by M. LALLEMAND and some other writers. This form of injection may be general or partial, and is much more characteristic of hyperemia than the second form, in which the redness is uniform. The gray substance is more frequently the seat of this second form of coloration; however, in some cases it may exist in the white or medullary portion. In the gray matter it presents a great variety of shades, from a deep red, similar to that of mahogany, to a light or delicate rosy tint, and it has been observed to occupy either the substance forming the convolutions, or the gray matter which is disseminated through the different points of the cerebro-spinal mass.

In the greater number of cases of cerebral congestion, the anatomical changes are not confined to the brain alone; its membranes show at the same time more or less marks of hyperemia; the meninges are usually more injected than natural, and the veins of the pia mater in particular are large, and distended with a quantity of dark-looking blood; the sinuses of the dura mater are also engorged, and the whole organ bears marks of the irritation which has occupied it. In some cases we find troubled, sometimes clear, serum in the ventricles, or in the cellular tissue beneath the arachnoid; sometimes, on the contrary, the surfaces of the brain are free from humidity, and the serous membrane in particular seems to be in an abnormal state of dryness. We must attribute the presence of the serosity now alluded to, to an interruption of the circulation through the brain, in a word, to a mechanical cause, and when the congestion has been carried to a very high degree of intensity, we may find not only serum, but blood, effused from the vessels. It is necessary, however, to remember, that the blood is not effused into the nervous pulp, but into the cellular tissue, by which the different parts of the brain and its various fibres are surrounded and supported.

We have now laid before you a rapid sketch of the several anatomical forms under which cerebral hyperemia may present itself, but it is of importance to observe that, in order to determine after death whether the phenomena we witness really belong to true hyperemia or not, you must take into account the two following circumstances. In the first place, you must take into consideration whether the patient has

died of an acute or a chronic disease, for in individuals who are rapidly cut off by the former, the different parts of the cerebro-spinal axis are more injected than in those who die at the termination of a chronic malady; thus, in two patients, one of whom has died of acute pneumonia, the other from phthisis, the brain may exhibit very different degrees of injection. In the second place, we should be acquainted with the nature of the individual's death, as, for example, whether he died from asphyxia, &c. In this case we know the injection of the cerebral substance is always well marked, and cannot be regarded so completely as a pathological condition, as if the same degree of coloration were observed in a person who died of a tubercular affection. Finally, we should pay attention to the circumstance that some parts of the brain in a normal state are more deeply coloured than others; thus the gray substance appears much less vascular than the white; the cerebellum than the cerebrum; and, on the other hand, the age of the individual is not without some influence on the degree of injection in different parts of the brain; in the infant the white substance contains more vessels than in the adult; and in the adult more than in the aged person; and hence the brain of old persons, which presents the same degree of injection as that of a child, ought not to be regarded as being in a normal condition.

Influence of Temperature &c. on the Brain.

Let us now turn to the causes which promote the development of hyperemia of the cerebral hemispheres; and, first, as to the exterior world. In what manner does the atmospheric temperature influence the production of this disease? for, that it has an influence, and a very considerable one, we cannot permit ourselves for a moment to doubt. Experiments made upon animals, and the observation of certain cases in man, prove indubitably that an elevated temperature is one of the most powerful causes of cerebral congestion. Let us then examine, in the first place, the effects of heat. If we take a range of between twenty and fifty degrees (centigrade), and above fifty degrees death rapidly ensues,—if I say we assume this range as representing an elevated temperature, we shall find that in from fifty to forty degrees the economy may either resist the heat, or the individual dies rapidly, with all the symptoms of cerebral hyperemia. In from forty to thirty degrees the same phenomena are observed, but the congestion is usually less intense. In some cases, where death has ensued from exposure to a heat at this degree, nothing has been found but a simple congestion of the brain; in others, blood was effused into the substance of the cerebral mass. You will find many examples of this kind in the following

Medicale, vol. 70, page 250. In proportion as the temperature descends, the accidents of which we speak become more and more rare. We may observe them at from thirty-five to thirty degrees, but at from thirty to twenty the tendency to cerebral congestion disappears, and within this latter limit its frequency ceases to be in direct proportion to the elevation of the temperature. Thus, gentlemen, an elevated temperature certainly has an influence in the production of cerebral hyperemia. I need only cite in proof the fact, which has frequently been witnessed in the course of very hot summers,—viz. the sudden death of reapers and other individuals employed in collecting in the harvest.

Again, a very low temperature has also a powerful influence in determining congestion of the brain; indeed, we may say a greater one than heat, if we except artificial temperature, and regard only the effects of climate. Thus, in Holland, it has been shown that cerebral congestions are more frequent in winter than at any other season; this has been determined from a statistic of twenty years;* and at Turin, observations made with the same object for twenty-five years lead to a similar result.† Finally, who does not remember the unfortunate history of the retreat of our armies from Russia during a season of unexampled severity? M. LARREY and the other surgeons inform us, that the greater part of the persons who died during that retreat were affected at first with vertigo, stupidity, &c., and then fell into a state of somnolence, followed by coma and death.‡ Persons who pass suddenly from one extreme temperature to another, are also exposed to cerebral congestions.

There are cases in which we see this hyperemia declare itself suddenly, without any known cause, in a number of individuals at the same time, and reign in a manner altogether epidemic. M. LEVRET has published some interesting cases of this kind, which you will find in the *Journal des Progrès*, 2nd series, vol. 2. Three individuals were suddenly attacked at Charenton with the symptoms of cerebral congestion; two died, and the substance of the brain appeared excessively injected, without any other alteration: at the same time many other individuals in the neighbourhood presented some slight symptoms of cerebral embarrassment. M. LEVRET could discover nothing to explain the circumstance, except a very strong south-west wind, which had prevailed during several days.

With regard to electricity, I have very little to say. Observations are wanting to enable us to form a decided opinion; however, we may mention the case cited by a foreign

physician, in which electro-puncture was practised; at the moment the needle was placed in communication with the electric fluid, the patient experienced a sensible pain in the head. We may apply the same remark to the influence of light in the production of hyperemia, as we have just done to that of electricity. We do not possess sufficient data to form a judgment; all we can say is, that only one-sixth of cerebral congestions commence in the night.

Effects of Stimulants and Narcotics.

The effects produced by alimentary substances on the development of hyperemia, have been considered by some writers as demonstrated; we can conceive how a rich and exciting diet may, by generating a greater quantity of blood in the system, favour a determination towards the head; but we think, that at the same time a predisposition must exist on the part of the individuals. On the other hand, alcoholic drinks have, beyond all doubt, a powerful influence in the production of the congestions under consideration, and we are induced to think that they may act not only sympathetically from the stomach, but also exercise a direct influence on the brain itself: this is the more probable, because after death the odour of alcohol has been found disseminated through the substance of that organ. Narcotics also may have a direct influence in determining cerebral hyperemia; no matter how introduced into the economy, or under what form, as opium, belladonna, tobacco, or prussic acid, we always find after death an identical lesion, consisting in a greater or less hyperemia of the nervous centres. But these congestions have something special in their character, something which prevents us from regarding the anatomical lesion as the whole disease. Observe cases of poisoning produced by narcotics, and you will convince yourselves that the brain must be the seat of modifications, which the scalpel indeed does not reveal after death, but which are proved by the diversity of the nature of the accidents that occur during life. A question which has long occupied physiologists with regard to the action of the substances now alluded to is the following:—"Do the special symptoms produced by each of these substances, depend on the influence each exercises on a special part of the brain?" If we rely on the experiments of several physiologists who are worthy of confidence, we must resolve this question in the affirmative, and believe that opium most readily produces congestion in the hemispheres of the brain, alcohol in the cerebellum, nuxvomica in the spinal marrow, and belladonna in the tubercula quadrigemina. This latter fact especially would seem to result from the experiments of M. FLOURENS: but we must remark, that all these deductions have been drawn from

animals, and that the observations hitherto made on the human subject, have neither confirmed in a sufficient manner, nor, on the other hand, have disproved, the results at which experimenters have arrived.

Congestion from Causes within the Brain.

Internal causes have a far greater and more extensive influence than agents which operate from the external world; we can discover various conditions of the brain itself that favour in the most evident manner the production of cerebral congestion: thus a forced exercise of the intellect, long-continued and severe study, powerful emotions, such as fear and joy, the passions, &c., may in turn give rise to the several accidents that characterize hyperemia of the nervous centres. It is unnecessary to cite examples in support of this assertion: you will find them in every author; and your experience cannot fail to have furnished more than one proof. *Certain diseases* of the brain, again, have the effect of determining in the organ a degree of congestion which has erroneously been regarded as the cause of the malady itself; as in epilepsy, which disease certainly does not depend upon a simple hyperemia of the brain, although the congestion which accompanies or succeeds each access, may become the cause of certain accidents that we observe in epileptic patients. It is on this principle that we would explain the comatose state which often persists for a greater or less period after the access; the troubles of intelligence, delirium, &c.; certain disorders of movement, as paralysis, contraction of the muscles; and, finally, various other symptoms of cerebral derangement. Accidental products in the brain, as tubercles &c.; the cysts which succeed on old apoplectic effusions, hydatids, and several other products of the same kind, may all act as so many centres of irritation, and give rise from time to time to an hyperemia, varying in intensity and extent according to the cause which produces it. When congestions take place round the foreign bodies, as we may so call them, two orders of symptoms arise; the first are often permanent, and depend on the presence of the accidental product. The second are intermittent, like their cause, and are produced by an occasional congestion round the point of irritation. It is thus that we would account for the intermittent convulsions of children affected with tubercles of the brain, giving rise from time to time to accesses of hyperemia, and this is a remarkable example of intermittent phenomena produced by a permanent organic lesion. Finally, the different degrees of *meningitis*, especially when the disease is chronic, may often give rise to corresponding congestion in the neighbouring portion of the cerebral hemispheres.

From Derangements in other Organs and Systems.

The *causes external* to the brain are next in order. The influence exercised by the different organs, whether healthy or in a state of disease, on the production or relapse of cerebral congestions, merits our attention. And first for the digestive tube.

We may affirm, without danger of error, that certain acts of the *stomach* may occasion the development of cerebral congestion, particularly in individuals who are predisposed: thus, a too active function of digestion has more than once been the cause of relapse. May we not refer the sleepiness affecting certain individuals after a full meal, to a slight degree of the same congestion? A *pathological condition* of the stomach does frequently, and beyond all doubt, exercise a manifest influence in the production of cerebral hyperemia. Thus, in childhood, acute inflammation of the stomach and bowels may be accompanied by accidents that announce the existence of congestion in the brain; however, though we are willing to allow the cerebral effects of excitation in the digestive tube, all we shall say, with respect to typhus fever, is, that here possibly the inflammation of the mucous membrane *may* be the cause of cerebral congestion, as it frequently accompanies that disease.

A *chronic affection* of the *intestinal canal* may likewise produce congestion of the brain; but much more rarely than acute gastro-enteritis; however, we cannot doubt its influence in some particular cases. Thus I have had occasion to treat a lady, in whom the ingestion of alimentary substances in too great quantity invariably gave rise to cerebral symptoms; the face became coloured, she was affected with severe headache, ringing in the ears, weakness and numbness of the arm, and even loss of memory: these symptoms sufficiently indicate an excess of blood in the brain, and what is remarkable, they never appeared except in consequence of some error of regimen. In another case, that of a patient labouring under chronic gastritis, every time the affection of the stomach became exasperated, the patient was seized with paralysis of the arm.

Irritation of the small intestines may also be arranged amongst the undoubted causes of cerebral hyperemia. Who is unacquainted with the effects of prolonged constipation in determining the blood towards the brain?

The *circulatory apparatus* may, also, by its various conditions, produce different degrees of cerebral congestion. It is easy to conceive how the various degrees of force with which the blood is carried to the brain influence the development of hyperemia in that organ. We have frequently seen patients subject to the various affections of the heart, in whom the action

tion of the circulating medium is accompanied with giddiness, ringing in the ears, and other symptoms of congestion in the brain. Again, any obstacle to the free return of blood from the head may give rise to a similar result. Sometimes the impediment exists within the cavity of the cranium; the researches of Dr. TONNELLE prove in a striking manner the coincidence of hyperemia, and even cerebral hemorrhage, with an obliteration more or less ancient of one of the sinuses of the dura mater. (*Journal Hebdomadaire*, April 1830.) M. GINRAC, of Bordeaux, has related a case in which the congestion was caused by an obliteration of the longitudinal sinus. A tumour pressing on the jugular vein may also become a cause; and the congestion observed in malefactors who have been hanged, evidently depends on the same circumstance, viz., a mechanical obstacle to the free return of blood from the head. A change in the circulation of the brain is often produced by very slight causes: thus in some individuals, a mere change of position from the vertical to the horizontal posture, and *vice versa*, is enough to occasion vertigo, and some persons can never get up or lie down in bed without experiencing a similar sensation.

The disease termed *apoplexy of new-born children* may be, in most cases, attributed to an obstruction of the venous circulation from the brain; and instances are on record where death has been produced by the pressure of the chord round the child's neck, causing a fatal congestion of blood. Finally under this head, we may arrange the effects of certain violent efforts, such as the act of vomiting, defecation, &c.

The different *organic diseases of the heart*, which oppose the free return of blood from the head, or by turns retard and accelerate the circulation in a remarkable manner, must also be ranged amongst the causes that give rise to cerebral hyperemia. Nor are we to neglect the influence evidently produced by simple acceleration of the circulation during the course of ordinary or intermittent fevers. We cannot certainly explain in any other manner the headache, giddiness, pains in the limbs, &c., which accompany every access of fever at all well marked.

The development of cerebral congestion is also favoured by the existence of *inflammation in some other organ*. You know that congestion forms one of the elements of inflammation, and this element may be repeated in the brain under three different circumstances, which we shall now enumerate. 1st, Before the inflammation takes place in the organ; as for example, in measles, small-pox, and scarlatina, when we only observe the existence of delirium, or even coma, during the febrile access, and the appearance of the cutaneous eruption. 2nd, At the same

time as the inflammation; witness erysipelas of the scalp and face, which is often fatal, with cerebral symptoms, leaving no other trace of lesion in the brain, than an hyperemia more or less well marked. 3rd, The symptoms of congestion may set in after the inflammation has completely disappeared; of this we may cite examples in the congestions that follow the disappearance of a cutaneous malady, the sudden retrocession of erysipelas of the face, &c.

There are, again, cases in which we in vain seek the cause of cerebral congestion in the access of intense fever, or in the inflammation of another portion of the body: here it depends on a certain congestional diathesis, if we may so use the expression,—on a *morbid condition of the system*, in which the different organs become in turns congested. We have seen cases where the nasal fossae, the uterus, the lungs, the intestinal canal, and the brain, have shown symptoms of congestion, one after the other, without our being able to discover any thing in the patient's constitution or mode of life to explain this singular phenomenon. Having thus studied the effects produced by various conditions of the solids, we may ask ourselves whether the *quality* of the blood exercises any influence on the production of symptoms of hyperemia of the brain. We cannot doubt but that persons whose blood contains a great deal of fibrine and colouring matter, in a word, individuals endowed with what is called a sanguineous temperament, are predisposed to cerebral congestions; but on the other hand, the absence of this temperament by no means ensures a patient against the dangers of hyperemia, a disease which, as you have seen, may be occasioned by so many other causes.

Affections of the *respiratory apparatus* can rarely enter amongst the causes of congestion of the brain; we can only admit them as such when they produce an obstacle to the circulation, as in asphyxia or croup, and then they are to be ranged under some of the categories already mentioned.

With regard to the *secretory apparatus*, I may observe, that when in a normal state, the different secretions do not seem to exercise any remarkable influence in favouring the development of the disease which now occupies our attention. However, in certain morbid conditions, as for example, on the suppression of a discharge to which the economy has been for a long time accustomed, they may undoubtedly give rise to a determination of blood towards the head. Some writers have greatly exaggerated the effects arising from the stoppage of suppuration, whether once artificially excited, or originating in an accidental lesion. Although I would not deny that such effects may sometimes take place, I am inclined to think that much greater value has been attributed to this circumstance than it really deserves.

The *genital apparatus* is the last whose influence in cerebral congestion we have now to examine. The reproductive organs, gentlemen, give rise to frequent derangements of the circulation in the brain, as well as in several other parts of the economy; this is particularly seen in young females as they approach the age of puberty. How many accidents dependent on cerebral hyperemia do we witness in young females at the period of their first menstruation! And at the decline of life, when the normal stoppage of the menstrual flux is about to withdraw the constitution from an influence to which it has been habituated for a long series of years, how often do we see the same phenomena repeated! Finally, in suppression of the catamenia, it is not an unusual thing for the patient, at each period, to exhibit the various symptoms that indicate a more or less severe congestion of the brain.

These are circumstances, gentlemen, that you should never neglect in practice; and above all things, watch with anxiety and care the signs of congestion towards different organs, particularly towards the chest, in some young girls, at each period of menstruation; be on your guard here, I say, or you may render yourselves culpable of a fatal neglect; for in too many cases, the periodical determination to the thoracic viscera awakens a latent disease, which, when once advanced, leaves the patient without hope, and medicine without a resource. The different degrees of intensity with which an individual may abandon himself to the generative act, also enter amongst the causes of cerebral hyperemia. Thus an abuse of venereal pleasures may become a curse, and, on the other hand, a similar effect may arise from complete abstinence.

With regard to the influence of age, I may observe, that individuals at every period of life, from infancy to decrepitude, are subject to the disease which has just occupied our attention; but we do not think it proved, as many writers have advanced, that cerebral congestion is most common in old age. We have collected numerous examples in children of the tenderest infancy, and think the only conclusion warranted by facts is, that the maximum of intensity may be placed after the age of forty.

We have now, gentlemen, touched upon some of the principal causes which give rise to congestion of the centre of the nervous system; and in reviewing them, with the design of adopting some general classification, we find that they may be comprised under three heads. Thus many cases of congestion of the brain are evidently produced under the influence of certain mechanical forces, and this is a circumstance which can be very readily understood. Other causes act by producing a modification of force in the circulation of the brain itself; the blood is carried to that organ with greater rapidity

and in greater quantities than is natural, and congestion is a frequent consequence of this state. Finally, in other cases of cerebral congestion, we have a diminished activity of the vessels of the brain; the quantity of blood which circulates through that organ is reduced in quantity, and this circumstance often gives rise to functional disorders exactly similar to those occasioned by the presence of a superabundant quantity of blood. Thus, then, we have three species of causes engaged in the production of cerebral congestion; some are purely mechanical, others are active, and others are much less active or are even passive; and the three conditions resulting from the operation of the above-mentioned influences may, with advantage, be distinguished into mechanical, active, and passive hyperemia.

The Symptoms of Cerebral Congestion.

Having thus taken a brief review of the causes of cerebral congestion, let us now, gentlemen, pass to a consideration of the symptoms accompanying the disease. These are extremely different in different cases, and vary according to a multitude of circumstances which it is not always in the power of the physician to seize; we may, however, lay it down as well established by observation and experience, that the symptoms of cerebral congestion vary according to three principal circumstances: the first is the intensity of the lesion, which produces a variety in the symptoms of all diseases in general; the second is the duration of the congestive state; thirdly, and finally, the symptoms vary according to the diversity of the points of the nervous system which may be affected. These are the three main circumstances, gentlemen, according to which the symptoms of cerebral hyperemia are at one time well marked, at another obscure, and present the great diversity of appearances which render it so difficult in many cases to form a certain or correct diagnosis in diseases of the nervous system. With regard to the last circumstance, namely, the diverse points of that system in which congestion may exist, we are compelled, for the sake of order and clearness, to study, separately, congestion as it may occur in the cerebral hemispheres (or brain), in the cerebellum, and in the spinal marrow. The first of these may present itself under a variety of forms, each of which we shall describe apart, and endeavour to point out the most striking characters by which it is distinguished from the others.

First Variety of Cerebral Congestion.

In the first form of congestion to which we now direct your attention the great functions of the brain remain intact, the intelligence is clear, the reasoning undisturbed, the memory and other faculties are altered: this is the most dangerous form indeed.

we observe may all be referred to lesions of the sensibility, which is but slightly deranged. The principal modifications of sensibility characterizing this simple form of hyperemia are, pain in the head, which is sometimes carried to a very severe extent; vertigo; ringing or singing in the ears, momentary aberration or loss of sight, giddiness, &c. The locomotive powers are at the same time variously affected: in some cases you find the movements executed with dullness and evident disinclination; the patient is heavy and inclined to sleep; while in others he is tormented with a constant desire of exercise, he is constantly on his legs, and cannot rest for a few moments without experiencing a troublesome feeling of anxiety and restlessness; in other cases, again, you will remark nothing but some fourmillemens in the limbs, or sometimes about the face. In certain cases the local symptoms seem to affect especially the circulatory apparatus. At the same time that the patients present many of the symptoms of cerebral congestion, they are attacked with frequent and violent palpitations of the heart, throbbing of the arteries, &c.; but observe, gentlemen, that these palpitations may occur under two very different circumstances, which it is of some importance to distinguish; in one the trouble of the heart and circulatory apparatus is evidently dependent upon the derangement which has taken place in the nervous system, because it does not manifest itself until some time after the symptoms of congestion in the brain; in other cases, on the contrary, the palpitations are connected with some condition of the heart or vascular system, giving rise to increased energy of action in that organ, and subsequently to congestion of the cerebral vessels. The influence of this latter cause is manifest in a great number of cases which we have witnessed. We have frequently seen individuals in whom any slight augmentation of the palpitations to which they were ordinarily subject, was constantly attended with giddiness, vertigo, singing in the ears, or even a well-marked sensation of numbness in the extremities of the fingers. Hence we are compelled to admit that in a certain number of cases the palpitations of the heart, to which we have just alluded, may either follow the derangement in the nervous centre, or be the cause of congestion, by the increased force with which the blood is sent to the brain. It is unnecessary for me to point out the importance of this distinction in a practical point of view.

When congestion of the cerebral hemispheres is carried to any remarkable degree of intensity, the symptoms become more general, the economy at large seems to be affected, the measure of the disturbance is increased, the temporal arteries now beat with considerable force; in some cases

so violently that their pulsations may be recognised by the eye as well as the touch; the cheeks are suffused with a brilliant red colour; the vessels of the ocular conjunctiva become injected; even the forehead sometimes partakes of the coloration of the face, and the whole veins of the head show marks of congestion; the small and large branches are equally distended with blood. In this state of the circulation hemorrhage may take place from the vessels of the nares, and dissipate all the unpleasant symptoms; or congestions may form in various other parts and organs of the body, giving rise to a number of secondary accidents; for, like most other diseases, cerebral congestion may exist singly, or be complicated with a variety of other lesions.

The species of cerebral hyperemia which now occupies our attention may present itself under two varieties, according as it is accompanied by signs of febrile reaction or not,—according as it exists with what is called inflammatory fever, or is not attended with any symptoms of general derangement of the circulation. In the first case, when congestion of the brain is attended with fever, its duration is generally very limited: in the second, its duration is indeterminate. Thus, in some cases, the disease does not seem to exist beyond a few hours, after which the headache, giddiness, and other symptoms, completely disappear. In other cases, the signs of cerebral hyperemia may continue with little or no intermission for several months, or even for whole years together; thus, I have seen patients who showed the first symptoms of congestion in the head, at the age of twenty, and still continued subject to more or less severe attacks, up to the age of forty, fifty, or fifty-five, or even during the whole life. The duration, then, of this disease is very uncertain, and may, in certain cases, be prolonged to a great length of time. Sometimes the congestion is, as it were, permanent, the patient is constantly affected with giddiness, pain in the head, noise in the ears, &c.; but more frequently it becomes suspended for an uncertain period of time, and then returns under the influence of causes which we can occasionally appreciate, but which in many cases escape discovery altogether.

Congestion of the brain is a disease of very frequent occurrence, and when once a patient has been affected with it, the chances that he has it again are very numerous; the period of relapse is, as we have just noticed, at one time uncertain; at another, the congestion recurs at fixed periods, at the change of life, as it is called, at certain changes of season, &c. I remember the case of a patient who, during the course of several years, was attacked towards the end of every winter with symptoms of severe congestion of the brain. The accidents per-

sisted from twelve to fifteen days, and then went off, to return again at the same period on the following year. In some cases the periods of relapse are so regular that the disease bears all the characters of an intermittent fever, so far at least as periodicity is concerned; and on examining authors you will find examples in which the access simulated that of a quotidian or a tertian ague. MEAD has left us the history of a man who fell down in a fit of apoplexy every year about the month of March; sensation and motion were completely lost for a few minutes, after which the individual returned to himself, but for ten or twelve minutes more he was unable to speak, and was affected with a trembling motion of the right arm; these symptoms were quickly dissipated, and the patient recovered the use of all his functions. When the return of the congestive state takes place at short intervals, it constitutes what many authors have called "intermittent apoplexy," a form of disease of which I myself have witnessed some very striking examples, and which often gives way rapidly under the administration of quinine in elevated doses.

This first and simple form of cerebral congestion may be succeeded by various others, or if it be prolonged for any considerable period of time, it may give rise to hemorrhage into the substance of the brain, or ramollissement, but in the majority of cases it may be dissipated by the assiduous employment of means which we shall have occasion to notice presently: its characteristic marks are, the intelligence intact, sensibility but slightly modified.

Second Variety of Cerebral Congestion.

Let us now take up the *second* form of congestion of the cerebral hemispheres. In this variety of the disease, the individual, either after having suffered for a greater or less period from giddiness, confusion of sight, and other symptoms of congestion, or without having previously experienced any of these accidents, suddenly falls down, deprived of all consciousness. This form of the malady is hence called a "coup de sang," and is characterized, as we have just said, by an instantaneous loss of consciousness, with or without previous symptoms. The patient suddenly falls to the ground, deprived at once of intelligence, of motion, and of sensation, as if hemorrhage to a considerable extent had taken place in one of the cerebral hemispheres; however, it is distinguished from this latter affection by the circumstance that it is very rarely accompanied by hemiplegia; the symptoms connected with locomotion, in cases of cerebral hyperemia, are much more frequently those of general paralysis than hemiplegia. Sometimes, however, although the individual lies without motion and consciousness, the limbs are not, properly speaking, struck

with paralysis. When raised up they do not fall down in that dead helpless manner which distinguishes palsy, but may even remain elevated.

In the second form of cerebral congestion death may suddenly take place; the coup de sang carries off the individual as rapidly as an access of apoplexy; in other cases the attack may last for some hours; the patient may remain in a comatose state from a few minutes to twenty-four or thirty hours; nothing is more variable. Finally, in other cases, the accidents go off by degrees; the intelligence, motion, and sensation, are gradually re-established, and, after a lapse of time which varies as much as the duration of the attack itself, the patient is restored to the full enjoyment of his health. It is astonishing to see how rapidly the recovery may take place from a state in which the patient has lain, perhaps for a considerable time, without consciousness, power of motion, &c.,—in a word, with all the symptoms of an apoplectic stroke; yet such a case frequently occurs in practice; and we find the individual, whom we left labouring under the most alarming symptoms, restored to perfect health, without any lesion of movement or sensation being left behind. I cases of this kind, we are certainly forced to admit the existence of simple hyperemia of the cerebral substance; we cannot for moment imagine that actual hemorrhage has taken place, for the sudden and perfect recovery of the functions is quite incompatible with the latter supposition. General paralysis, then, as contra-distinguished from hemiplegia, or loss of motion in one side of the body, is the characteristic symptom of the form of cerebral congestion which we have just now described under the familiar denomination of "coup de sang."

I said that the patient sometimes recovers unexpectedly from the state of coma into which the undue determination of blood to the brain has plunged him; this is not always the case; on the contrary, the accidents often persist in a greater or less degree, and consist in lesions of the intelligence, of motion, or of sensation, the three great functions of the life of relation. Thus after the patient has recovered from the first alarming effects of the coup de sang the intelligence often remains dull and obtuse; the patient has an air of stupidity, looks frightened; he is unwilling to be disturbed, or to walk about; in some cases even, we observe delirium; these symptoms may persist for four, five, or six days, and then the patient recovers the full exercise of his intellectual faculties. The sensibility may likewise remain affected; the patient conserves for some time a sensation of numbness in different parts of the body, the extremities particularly; he is sometimes with prickings in the limbs, and a severe headache is the only complaint while

remains, and this may persist with some intensity for a considerable length of time. Finally, gentlemen, certain patients present merely a derangement in the organs of locomotion; thus some are affected with weakness of the limbs, incapability of executing with force the ordinary movements, and this is remarked especially in the abdominal extrinsecities; others are unable to speak clearly for some time after the coup de sang; the impression seems directed entirely to the muscles of the tongue, and articulation is consequently imperfect and embarrassed; this latter symptom is frequently observed as a consequence of simple congestion of the brain; however, when the accidents which we have just enumerated persist for any length of time, we have reason to conclude that something more exists in the centre of the nervous system than mere congestion; the obstinacy of the secondary symptoms would indicate the presence of a permanent cause—viz. cerebral hemorrhage.

Third Variety of Cerebral Congestion.

Let us now turn to the third form or variety under which hyperemia of the brain may present itself. In this form we observe precisely the same accidents of intelligence, motion, and sensation, as in the former one, but we have something more than the general resolution of the limbs, which we give as the characteristic mark of the second variety; we here remark a phenomenon that connects cerebral congestion with hemorrhage—viz. hemiplegia, and this circumstance frequently gives rise to great difficulty in the diagnosis. I have seen patients struck with the coup de sang who suddenly became hemiplegic, and presented a combination of all the symptoms that are produced by cerebral hemorrhage, but these were dissipated in a short time by the ordinary means; here we cannot admit the existence of hemorrhage into the substance of the brain; it is impossible to conceive that a clot of blood should be removed in a few hours; the accidents can only be attributed to congestion, and we are compelled to allow that a symptom which is almost exclusively attached to effusion of blood into one of the hemispheres, may also present itself in conjunction with a simple determination to the head. This sort of paralysis is often seen after attacks of epilepsy, where the congestion which accompanies or succeeds the disease, frequently gives rise to certain disorders of movement; and, independently of the rapidity with which these accidents disappear, we have further reason for referring them simply to congestion, from the fact that the state of the circulation in the brain, after the access, not infrequently leaves no effects on the patient's countenance. In some cases, the patient presents redness on the conjunctiva, which disappear in three

or four days. Hence, whenever the accidents which succeed an attack of the kind we now describe, do not persist beyond the space of a few days, we may rigidly conclude the absence of any hemorrhage into the substance of the brain.

The hemiplegia accompanying this third form of cerebral congestion may disappear nearly as rapidly as it was produced, or it may continue for an indefinite time after the complete restoration of the intellect and other functions, and in this latter case we must attribute it to something beyond congestion; the persistence of the loss of motion infers the operation of some permanent cause, which is an effusion of blood from the vessels of the brain, that has accompanied or been caused by their state of congestion. The observations which we have just made, tend to establish that hemiplegia is most commonly connected with cerebral hemorrhage, while general paralysis or resolution of the members is more frequently observed with simple hyperemia of the brain; we must not, however, generalize too rapidly, especially in diseases of the brain. The cases published by M. LEURER, show that hemiplegia may exist with nothing but an abnormal injection of the vessels of the brain. I could find, perhaps, fifty similar cases in the science, which demonstrate the same fact, and hence we are compelled to draw a conclusion, which indeed will frequently present itself to us during the investigation of diseases of the nervous system—viz., that functional derangements are not always accompanied by changes of structure appreciable to our senses, and that in the case before us, some impression remains in the nervous system, causing a derangement of locomotion long after the coup de sang has passed away.

I should not forget to mention that in infants and children this form of cerebral hyperemia is chiefly shown by convulsions, and not by the production of general or partial paralysis.

Fourth Variety of Cerebral Congestion.

Now for the fourth variety of congestion. In this form, the intellect remains intact; the only phenomena we observe are modifications of sensibility or motility; and let me here remark to you a fact which is well worthy of attention, namely, that in a great number of diseases of the brain the intellect remains unimpaired amidst lesions which apparently should have produced its complete destruction. Here then we have no loss of consciousness as in the former varieties. The first symptom which shows itself is paralysis, often confined to some muscles of the face, but in other cases extending to the whole of one side of the body. This paralysis often disappears in a rapid manner, a few hours after its production;

and here certainly we cannot attribute it to the effects of cerebral hemorrhage. Some very curious cases have been published, which illustrate the progress and termination of this form of congestion; perhaps one of the most remarkable is that we owe to M. Gintrac, of Bordeaux,* of which the following is a brief account: "A child, four years of age, had been attacked from birth by an affection which consisted in a momentary suspension of voluntary motion, that came on at intervals; the access was not preceded by any premonitory symptoms. If the child were standing up when seized, his limbs bent under him, the trunk gave way, and he fell down at once on the ground; when in bed, the access was announced merely by a complete relaxation of the muscles. During the attack or fit the senses appeared somewhat dulled, and the sensibility was diminished; the eyes remained open and immovable; the sense of hearing remained; the intellectual faculties were perfect, but the child was unable to utter a single syllable. This child died of some other disease, and on examination, no alteration was found in the brain except the transformation of the superior longitudinal sinus into a hard chord, filled with a solid clot of blood." In this form, then, we have the intellect untouched, we have some modification of the locomotive power, and we have, finally, a suspension of some of the senses, while the others remain free from injury.

Fifth Variety of Cerebral Congestion.

In the fifth variety of cerebral congestion the lesion is chiefly directed to the intellectual faculties. Hyperemia of the brain, in this case, does not produce coma; it does not exercise any very remarkable influence on the movements of the body; the principal phenomenon is the sudden appearance of furious delirium, accompanied by an extraordinary development of muscular force.

This form of the disease is highly dangerous, and frequently compromises the life of the individual. In some cases the delirium is accompanied with so violent a perturbation of the brain that the patient dies in the access, vociferating loudly, agitated in the most severe manner, or making such powerful and long-continued efforts that life becomes extinct in the struggle. I have more than once been struck with the remarkable phenomenon of which I now speak. I have watched the case closely during life, examined the brain after death with the greatest care, and found nothing which could explain the excessive derangement of the intellectual functions, except marks of great congestion in the cerebral hemispheres.

In many cases this form of hyperemia, commencing in extreme delirium, and terminating in coma, or, more frequently, in an access of the most violent muscular efforts, has produced death as suddenly as if the patient had been struck by lightning. The autopsy reveals nothing but a vivid injection of the substance of the brain.

Different Symptoms from Similar Lesions.

These are the principal forms under which cerebral congestion may present itself to us; each you see has its characteristic mark. The phenomena accompanying each form are distinct, and on passing them in review we cannot help asking ourselves these questions,—“How comes it that the same identical lesion gives rise to such a variety of symptoms? Can we discover any principle to reconcile the apparent contradictions we meet with? Can we explain the diversity of functional lesion by a difference in the seat or duration of the organic lesion?” I think that a solution of the questions we have now put is chiefly to be found in the different parts of the brain which are affected; and that observations establish this general rule, that the discrepancy of symptoms which present themselves in the various forms of cerebral hyperemia depends not only on the duration of the malady, but still more upon the seat it may occupy in the central organ of the nervous system; but if you wish to know what particular parts of the brain are implicated when such or such symptoms appear, I must confess my ignorance: the state of the science does not yet permit me to arrive at the solution of this most interesting problem, although we have many excellent reasons for thinking that by it alone we can clear up the difficulties which now pursue us in our study of diseases of the nervous system.

Many attempts have already been made to localize the functions of the brain, but, I regret to say, most of them appear to be premature. Thus we have several observations which tend to establish that sensation and motion chiefly reside in the gray or cortical substance, and that when this portion of the brain is injured, the two properties just mentioned principally suffer. This may possibly be the case, but we have no proof of it, and until something better is offered than conjecture, we cannot think ourselves justified in coming to any conclusions; there are, however, some circumstances which lend it a colouring of probability. When the gray substance of the brain is injured, we certainly have no aberration of the intellect than when a lesion exists in other parts, and from the frequent occurrence of delirium in connection with meningitis, we might infer that the superficies of the brain is destined to the elaboration of ideas.

* Recueil d'Observations, Bordeaux, 1830.

faculties. We may, in fact, readily understand how the symptoms should vary according as the congestion may occupy the anterior portion of the brain, or the depth of its substance, or the various parts comprehended in the base of the organ. We can easily conceive a difference of external phenomena according as compression may be exercised on the corpus callosum, the thalamus, the pons, or the cerebellum; indeed, this ought to be the case, but, unfortunately, experience does not enable us to say how or when. Let us not however be discouraged, but hope for better times; let us examine with greater care, let us observe more, and, above all, collect a greater number of observations; for nothing can be more irrational than the error into which some writers fall of drawing general conclusions from two or three isolated facts, and attempting to explain phenomena before any solid groundwork has been established upon which they can build an hypothesis worthy of confidence or attention.

Affections of the Cerebellum.

The remarks we have hitherto made, refer entirely to one portion of the brain; but there is another part of that organ to which peculiar functions have been attributed, and many authors have thought that pathological observations ought to show whether these functions have justly been attributed to it or not. The part I now allude to is the cerebellum: some physiologists place the power which governs the organs of generation in the cerebellum; others connect it more particularly with locomotion, &c.; but if you examine the observations which are recorded in the different works upon diseases of the nervous system, you must perceive that many of these hypotheses are at least premature, and that we cannot refer to it a great variety of the symptoms which their authors would thus explain.

In some periods of cerebral congestion, we observe a certain number of symptoms which it is very difficult to connect with any particular lesion, or explain by any one of the hypotheses as yet formed; in these cases the individual looks exactly as if he were drunk; he is stupid, his appearance is extraordinary; when he attempts to walk, the organs of locomotion, though still capable of acting, are evidently deranged; his step is vacillating, and progression is performed by him in an imperfect manner and with difficulty. Here is a case in which we might suppose that the lesion was principally situated in the cerebellum, but we cannot affirm this with any certainty. We cannot bring forward any rigorous proof of it; indeed the observations which have as yet been made, are not sufficient for establishing that in this disordered state of the nervous system, the cerebellum is the part of the brain chiefly or solely implicated, and consequently undergoes

various modifications in the different forms of cerebral congestion, without our being able to attach any of its changes more particularly to one form than to another; sometimes it is exalted in a very extraordinary degree; the patient is unwilling to be disturbed, or the least touch produces an acute cry, as if the integuments were the seat of intense inflammation. Here, again, many writers will tell you that the cerebellum is the part of the brain chiefly attacked, but I must confess to you that I do not find this opinion confirmed, either by my own observations, or by an examination of the cases we possess. However, explain it as you will, the fact exists, and is not the less worthy of your attention.

There are also a certain number of facts connected with this part of the subject, of which we shall seize the present opportunity to speak, as they seem to throw some light on a doctrine, which, though not yet established, as I said before, upon proofs, yet has some probabilities in its favour. I have seen patients who at each return of the menstrual period (and in these cases the catamenia are always painful), were affected with more or less severe pain in the back of the head; this phenomenon was constant, and I possess three or four facts of the kind. Again, in one case, each time the individual had connection with a woman, he was seized with violent pain in the occipital region; this symptom constantly followed each act of copulation, and was accompanied by several other signs of cerebral congestion. In relating these cases, gentlemen, I merely give you facts as I have observed them; remember I do not connect them with any hypothesis or explanation. I have also had an opportunity of witnessing a case of priapism in a young man, accompanied by constant and very acute pain in the back of the head; this state lasted for three months, at the expiration of which time, I was sent for to see the patient, who had been suddenly attacked with alarming symptoms. On my arrival, I found him labouring under all the symptoms of acute meningitis. This patient died, and though I had an opportunity of examining the body, the fact is not less certain; besides, the inflammation of the brain was so well characterized, as to leave doubt of its existence. Here, then, are a certain number of cases in which we may presume that congestion of the cerebellum coexisted with a series of symptoms peculiarly connected with the generative apparatus, but I would not here build up any thing on so small a number of observations.

Congestion of the Spinal Marrow.

We now come to congestion of that part of the nervous system which is contained in the vertebral canal. Hyperemia of the spinal marrow is much less frequently met with than congestion of the central portion,

or brain. It may occupy various parts of the medullary column, and for arrangement may be distinguished into congestion of the cervical, of the dorsal, and, finally, of the lumbar portion. The symptoms which are connected with a congestive state of the spinal marrow consist entirely in lesions of movement and sensibility, together with a few that may be referred to derangements of organic life; the brain remains intact, and the intelligence consequently does not present any of those phenomena which so often accompany a similar pathological condition of the cerebrum.

Congestion of the spinal marrow may take place in a rapid manner, or may be formed gradually and slowly; let us first consider the rapid form. Here you may observe three varieties that we should distinguish from one another. In the first we have a special lesion of motility. The patient is suddenly seized with paralysis, which may affect the four extremities at the same time, or be confined to two of them, the superior or the inferior limbs. In some cases, however, which are excessively rare, the loss of motion may exist only in the members on the same side of the body; the patient is attacked with a true hemiplegia, but there you will generally find that the lesion has implicated the brain also, and that the spinal marrow is not the only part of the system which presents traces of congestion. The respiration may be compromised in cases of this kind, from paralysis of the muscles of the chest, of the diaphragm, &c., and the patient may die completely asphyxiated. The symptoms we have just enumerated, are in certain cases also attended with convulsive motions that are partial or general. In the second form of congestion of the spinal marrow the principal lesion is not manifested in the organs of locomotion, but in the sensibility. Sometimes we find a complete loss of sensation in various parts of the body; at others the modification of sensibility is shown by prickings, or a creeping sensation in divers points, by pains in the surface of the skin, or occupying the depth of a member. Finally, in some cases, these pains occupy the tracts of the nervous chords, and then simulate in a very close manner diseases called "neuralgia." In the third form we have a simultaneous loss of sensation and motion in the parts which receive their nerves from the portion of the spinal marrow that is affected.

Concluding Remarks on Cerebral Congestion.

These are the three principal forms under which hyperemia of the spinal marrow may present itself. The disease may terminate by death, and that rapidly, when the nerves which supply the respiratory muscles are gravely implicated; more frequently, however, the congestion is dissipated, and a cure

ensues. It produces, as you see, a series of symptoms which are almost exclusively connected with sensibility and motility. Its duration is very various; in many cases the symptoms continue for a length of time; in others we have seen patients who presented lesions of sensibility and motion for a considerable period, recover suddenly, and in a most unexpected manner.

You have now seen how congestion of the brain differs in different individuals according to the seat of the lesion, and its duration, and according to the patient's mode of life, occupation, and other causes, which it is the duty of the physician to investigate and estimate. You have also seen how it often terminates in death. When the disease, however, ends favourably, we may sometimes observe at the moment of its termination certain critical phenomena that are also found to accompany the close or decline of other diseases. Thus some patients are relieved from the headache, vertigo, and other symptoms of congestion in the brain, by a copious hemorrhage from the nostrils. This is a phenomenon very frequently observed, and must be familiar to you all. In other cases the unusual appearance of the menstrual flux dissipates the cerebral symptoms; I had a patient under my own care, who exhibited a curious phenomenon of this kind. She was frequently subject to attacks of congestion towards the brain, and each time the symptoms gave way on the appearance of a copious flux of serosity from the nose; the quantity of fluid thus discharged was really surprising, and was sufficient to wet three or four handkerchiefs in the course of the day.

Indications of Treatment.

Having thus laid before you, gentlemen, the several forms of cerebral hyperemia, and described the symptoms by which they are accompanied, let us turn to the therapeutic question, and point out the principal indications of treatment. There are three: the first, and perhaps I might say the principal, is to combat the cause which has produced or keeps the determination of blood to the brain; this is a point of the utmost importance, and without attention to it your other means will frequently fail; seek, then, I say, the cause of the disease if you would cure the patient. Examine the conditions under which he is placed, his mode of life, of nourishment, his occupations; weigh the influences of air, of season, of the inclement he may have taken; in a word direct your first attention to a removal of those causes which promote cerebral hyperemia. We have already treated of this at length, and we therefore refer you to what was then said on the subject.

After a due consideration of the cause, and the means of removing it, the next indication which naturally presents itself

to empty the vessels of the brain or spinal marrow. This is done by copious and repeated bleeding, according to the emergency of the case; the abstraction of blood may be performed with the lancet, or through the medium of leeches. Whenever the symptoms are threatening, the quantity of blood removed, to have any immediate effect, must be large, and I think venesection performed at the arm is preferable to any other mode. I have frequently seen the beneficial effects of his practice in cases where the headache, ringing in the ears, numbness of the limbs, &c., suddenly disappeared after the abstraction of a copious quantity of blood. If the patient have been subject to epistaxis, or any other habitual discharge; if the menstrual period be not far off, in case of a female: if the congestion have appeared in consequence of the repercussion of some cutaneous eruptions, &c., perhaps it may be sufficient to apply a number of leeches behind the ear, to the anus, on the inner surface of the thighs, or even around the navel; these, repeated according to the nature and gravity of the disease, frequently dissipate all the symptoms. However, you should not forget that in many other cases, after sanguineous emissions have been multiplied, the signs of congestion persist, or, fielding apparently, and for a short time only, to the loss of blood, they return again with renewed intensity.

The third indication is to draw off the afflux of blood, as far as possible, from the brain and spinal marrow; this is done by what are termed revulsives. The older authors contain numerous examples of the benefit derived from this method of treatment, and I have more than once had recourse to it myself with the most decided benefit. The class of medicines called revulsives are particularly indicated when the symptoms of congestion have succeeded the disappearance of a cutaneous eruption, or any chronic affection of the mucous membranes: in cases of this kind you must not neglect the previous existence of an irritation to which the economy has become accustomed. You must take into account the antecedent malady, and must endeavour to call it back by the repeated application of blisters and other similar remedies. Revulsion from the head may be attained by two principal modes of acting: 1st, by acting on the cutaneous surface, by blisters, the seton, actual cautery, and irritating ointments; 2ndly, by acting on the intestinal canal. Purgatives are one of the best means we possess for combating the accidents attendant upon cerebral congestion; I have had frequent opportunities of witnessing their utility, and I consider them even more efficacious than bloodletting in the most violent variety of cases. You may employ purgatives in two forms, either as cathartics, or as the object of pro-

ducing a powerful and instantaneous effect on the surface of the intestinal canal; or in a milder form, but long continued, so as to bring away two or three stools daily for a length of time. The former method we have frequently employed in cases where sanguineous emissions had not been attended with any success; a few drops of croton oil, or some other strong purgative, have been sufficient to dissipate accidents of congestion of a very severe nature, which had that persisted in spite of blood-letting from the arm.

CASES OF

MALIGNANT DISEASE OF THE TESTIS,

IN A CHILD AND AN ADULT.

To the Editor of THE LANCET.

SIR,—The enclosed account of two cases of malignant disease of the testis, was read at the *Hunterian Society*, on Wednesday last. I trust you will find it deserving of a place in your valuable Journal. I am, Sir, your most obedient servant,

GEORGE LANGSTAFF.

2, New Basinghall-street, Dec. 4, 1835.

MEDULLARY SARCOMA IN THE RIGHT TESTIS OF A CHILD TWELVE MONTHS OLD.

The child had from its birth been perfectly healthy, and its body was well developed. When about ten months old, an enlargement was perceived in the right side of the scrotum, which increased rapidly, and had, in the course of two months, acquired the magnitude and figure of a hen's egg.

The tumour had not excited any pain, nor was there any enlargement in the inguinal glands, nor any sign of constitutional disease. Its nature was ambiguous; it was elastic to the touch, but not of that peculiar transparency which characterizes hydrocele in a child. With a view of ascertaining its nature, the surgeon in the country who had the management of the case, thought it prudent to make a small opening, from which a little blood, mixed with a soft brain-like substance, escaped.

A few days after this operation, the child was brought to London, and placed under my care. I examined the tumour attentively, and from its elastic feel and configuration, I was at first inclined to think that there was fluid in the tunica vaginalis; but from its want of transparency, and having been informed of what escaped on paracentesis being performed, I suspected the disease to be of a medullary character.

I must confess, I never observed this disease in the testicle of so young a subject.

Mr. Lawrence was consulted. The point to be decided upon was, whether the disease should at once be removed, or whether a free opening should be made into the tumour, in order to ascertain its structure, before proceeding to the operation of castration. The latter method was pursued, an incision was made, and the tumour was found to be of a medullary structure, and, consequently, of a nature requiring immediate removal. Mr. Lawrence assisted me in the operation. There was considerable hemorrhage from the integumental arteries, which rendered it necessary to tie several of them.

The little patient did not experience the least subsequent ill effect from the severe operation, the ligatures came away, and the wound healed favourably; and in the course of fourteen days the child was sufficiently well to be removed into the country.

On the dissection of the tumour, the following appearances presented themselves:—The tunica vaginalis and albuginea were greatly thickened. The disease had its origin in the gland itself. Upon opening the tunica vaginalis, a tumour of about the size of a cherry was observed projecting from the anterior surface of the testis, and covered by the albuginea, which at this part was much attenuated by the progressive absorption caused by the growth of the tumour, which would shortly have burst into the tunica vaginalis. On cutting into the morbid growth, it was found to be composed of lobules of medullary matter, exactly similar to fetal brain, which is termed fungus hæmatodes. Not a particle of the natural structure of the testicle could be found, the medullary matter adhered but loosely to the tunica albuginea, which presented the appearance of a dense cyst. The spermatic chord was perfectly natural in structure.

(*Observations.*—As I am, from the result of long experience, led to believe that medullary sarcoma, carcinoma, and scrofula, are congenital diseases, I cannot help fearing that the disease in this case will attack some other viscus in the course of time; an occurrence which I have frequently witnessed. Yet there have been cases recorded where the disease was only local, which I sincerely hope will prove to be the fact in this instance.)

Since writing the history of this case, I have been informed by the professional gentleman who attended the patient after its return into the country, of the death of the child; he has also favoured me with an account of the symptoms after the operation, and the morbid appearances which presented on a post-mortem examination. These I shall briefly relate.

The child appeared to enjoy a good state of health for about four months from the time of the operation being performed. After this period a small tumour, of about

the size of a horse-bean, was detected beneath the scalp, near the posterior-superior angle of the left parietal bone. This tumour daily increased, and acquired the magnitude and figure of an apple. It felt soft and pulpy; but when pressed upon, pain was not evinced, and there were no signs of cerebral affection. The health of the child began to decline; the digestive organs became disordered, denoting some visceral affection; the abdomen was tumid, and an enlargement was, by the touch, felt deeply seated in the abdominal cavity. The patient only lived six months from the time the operation was performed.

Autopsy.—On opening the abdomen, a tumour was seen projecting into the cavity, from beneath the posterior surface of the peritoneum. On reflecting this membrane, the tumour was found to be formed by several of the absorbent glands, in the lumbar region, having been converted into medullary tubera. The abdominal viscera were natural in structure, and there were no signs of disease in the mesenteric glands, or in the glandula aggregata in the ileum.

The lungs on the right side were healthy, but those on the left were affected with medullary sarcoma. The brain was examined. On reflecting the pericranium, it was found highly vascular in the situation of the left parietal bone, and that bone was highly inflamed.

There was a tumour, corresponding in size with the one just described, on the internal surface of the parietal bone, which had detached the dura mater to the extent of the arch of the tumour. The arachnoid membrane lining the dura mater, and that reflected over the pia mater, were slightly thickened where the tumour protruded. The brain was natural in structure, and there was not any accumulation of fluid in the ventricles.

The heart was healthy.

The tumour situated beneath the scalp was presented to me by the gentleman who examined the body. The following are the appearances which were noticed on dissecting the morbid parts. The pericranium, which seemed to form the capsule of the tumour, was highly inflamed, as was the dura mater which contained the corresponding morbid enlargement. On making sections of the tumour, it was found to be composed of medullary matter, exactly resembling the testicle I had removed.

The external surface of the parietal bone, where the tumour was situated, as well as the internal, had been slightly acted on by the absorbents, but there was no communication between the tumours, except by the arteries and veins belonging to the parietal cranium and dura mater.

On opening a portion of the longitudinal sinus, I found the callus diminished by the protrusion of a part of the tumour on its

external space, which, in all probability, would, had the child lived a short time longer, have obliterated the canal in that part. I am induced to make this pathological deduction from having a preparation in my museum, where nearly the whole of the longitudinal sinus is obliterated by medullary matter. The preparation was taken from a patient who had been afflicted with tænia hæmatodes in various viscera.

HISTORY OF A MORBID TESTICLE.

In February 1831, Mr. S—, 30 years of age, a married man, requested my opinion respecting an enlargement of the right testicle. He informed me that it had been progressively increasing for nearly twelve months, and had affected his health, though he had had the advice of some of the most distinguished surgeons in London. Various means had been adopted to prevent the progress of the disease, which it is not necessary to describe, as they had no effect in checking the morbid action. Some of the surgeons advised him, as the only chance of saving his life, to submit to castration, which the patient at that time did not wish.

When he consulted me the testicle was of an immense size, and felt very dense and ponderous. There was considerable enlargement of the spermatic cord; the integuments of the scrotum were of a reddish colour, and the veins were greatly distended and tortuous, and meandered over its surface similar to what I have generally noticed in examining fungoid tumours. The inguinal glands were not affected.

Leeches were ordered to be applied frequently; iodine was employed internally and externally, and his digestive organs were well attended to. This plan of treatment, with little variation, was adopted for several months, without producing any good effect. The spermatic cord became greatly distended, and there were all the appearances denoting hydrocele. Paracentesis was performed; the fluid exactly resembled that of a hydrocele in the tunica vaginalis. This operation lessened the distention, as well as the pain which he had experienced; but the fluid soon accumulated again, and the operation was obliged to be repeated a great number of times. A seton was introduced into the scrotum, which occasioned a profuse discharge; this was continued for some time, but as it did not appear to alter the morbid growth of the testicle, it was discontinued. As the health of the patient began to decline, and he had a sallow complexion, it now became a question whether it would be right to propose the removal of the testicle. At this time Mr. Earle saw the patient, and his opinion was, from the appearance of the patient, and the character the tumour presented, that it was a malignant disease, and that it would be proper to cut him into a better state of

health before the operation was to be performed.

His health did not improve, and the pain became so distressing that he felt desirous to submit to the removal. Sir Astley Cooper was consulted, and his opinion was, that castration should be performed as soon as possible, with a hope of saving the life of the patient.

I performed the operation on the 23rd of April, 1833. The ligatures separated in about a fortnight, and the wound healed favourably.

The patient at this time, November 23rd, 1835, appears to be in good health, and says that he is, in every respect, as vigorous as ever.

Appearances of the Testis and Spermatic Chord.—A pipe was placed into the spermatic artery, and the parts were injected with size and vermilion. On dissecting the spermatic chord, there were seen several large serous cysts, not hydatids. On cutting open these cysts their internal surface was found to be minutely injected, which accounts for the rapid secretion of fluid which so frequently took place. The spermatic artery was very large, and the vas deferens was pervious from its origin at the epididymis. The tunica vaginalis and albuginea were greatly thickened by chronic inflammation, &c., and they were firmly adherent. A section was made of the morbid testis; there were no signs of the natural structure, and there was scarcely any appearance of vascularity. The morbid productions were composed of scrofulous tumours, which occupied the principal portion of the internal part of what had been the natural structure of the testicle. The external surface had all the characteristic signs of carcinoma; and exactly resembled some preparations of scirrhous testicles which I have in my museum.

Observations.—As the morbid structure of carcinoma, medullary sarcoma, &c. &c., and their devastating effects on the constitution, have been so ably described by distinguished pathologists, it would appear almost needless to publish any more on this subject, except with a view to detailing the minute anatomy which tends to elucidate the cause of those morbid changes, and the tissues which they affect, and this I hope will shortly be satisfactorily given by my friend Mr. Kiernan.

My motive for wishing to publish these two cases is, to show, in the first case, the early development of the disease,—its occurrence in a child, which appeared to be, otherwise, in perfect health,—and to point out the singular circumstance of its affecting so many other parts of the body, so soon after the operation,—a fact which proves what I have frequently asserted, viz. that malignant diseases and scrofula are congenital.

The second case is only interesting in one part of its pathology, and that relates to the combination of scrofula with carcinoma. This is a rare occurrence, and one which I should term accidental. I have inspected the bodies of a number of patients who have died from the effects of medullary sarcoma, and only in one instance did I find any sign of scrofulous tubercles, and they were in the lungs, and of the miliary kind.

I have seen such unfavourable results after operating for cancerous or fungoid affections, that I have determined never to propose an operation, or again to perform one, in either disease, unless at the particular desire of the patient, and with his consent to abide by the consequences, without reproach against the surgeon.

ON THE LAW OF MORTALITY

IN

EACH COUNTY OF ENGLAND.

By T. R. EDMONDS, Esq., B.A., of Trinity College, Cambridge.

(Concluded from page 371.)

In exhibiting the law of mortality of the aggregate population of England, I have gone to the full extent allowed by the materials, and compared the mortality in each of thirteen gradations of age. A comparison to the same extent might have been instituted for each county, but the results would have been less valuable, being founded upon observations of very inferior magnitude. According to the doctrine of chances, the smaller the number of facts, the less correct is the indication of the general law which these facts obey. When the intervals of age are very small, and when the differences between the mortality at consecutive intervals are also small, the true law of mortality is never correctly indicated, unless the facts observed are of immense magnitude. During infancy, the mortality at one annual interval differs 32 per cent. from the mortality of the succeeding annual interval; and on account of this great difference, a small number of observed facts are sufficient to determine the true law at this period. But between the ages of fifteen and fifty-five years, the mortality at any annual interval differs only one-thirtieth part from the mortality of the next annual interval; and we cannot expect to find any materials of sufficient amplitude to indicate correctly these minute differences. By extending the intervals of age observed, we increase the weight by diminishing the number of the results. We also thus increase the differences between the mortality at two consecutive intervals, which is a point of

considerable importance. For example, in two consecutive results, when the intervals are small, differ by the amount of 10 per cent., and other two consecutive results, when the intervals are larger, differ by the amount of 30 per cent., a much greater number of facts will be requisite for determining the approximate value of the smaller than that of the larger difference. For reasons of this nature, in comparing together the mortality of different counties, I have extended the intervals, and reduced the thirteen to five gradations of age. I consider that the numbers thus obtained are of nearly equal weight with the numbers obtained for the aggregate population in smaller intervals of age. No useful information has been lost by this proceeding, for I have taken care to draw the lines of division in such a manner as to include the parts most nearly allied to each other. To prevent the possibility of any mistake on this head, I have obtained for nearly all the counties of England, the resulting mortality for each of the thirteen gradations of age. As I have not met with one instance of a decided variation from the scale of relative mortality already exhibited for the aggregate population, there appears to be no reason for desisting the publication of the results for smaller intervals of age than those which I have adopted.

In classifying the different counties of England, I have arranged them principally according to the rate of mortality of females between the ages of fifteen and sixty years. But I have not separated counties in juxtaposition, when the difference in the rates of mortality was inconsiderable. The mortality of males at the same interval of age would not serve as a good index to the healthfulness of a locality, unless we could abstract the detrimental effect of their occupations, leading to fatal accidents, or to loss of health. In many counties, also, the uncertain amount of the military and maritime population, diminishes considerably the value of the apparent mortality of the male sex. Another valuable classification might be made, grounded on the mortality under the age of fifteen years, but much preliminary labour would be requisite, in order to abstract the influence of large towns. For example, the mortality in Devon, under the age of five years, is nearly 25 per cent. greater than in Cornwall, and yet it is doubtful whether the climate of Devon is less favourable to infant life than that of Cornwall. The greater part of the excess may be accounted for by the accident of Cornwall not containing a large town like Plymouth, the mortality of infants in large towns being nearly twice as great as in the adjacent country. A classification more valuable and more complex than that which I now present may be made hereafter, when much local knowledge has been concentrated on the subject.

TABLE showing for each County of England the Annual Deaths which occur for every Hundred Living in each of Five Gradations of Age, the Counties being Classified according to the Mortality of Females between the Ages of Fifteen and Sixty Years.

The numbers representing the mortality in thirty-nine counties, have been obtained by increasing the registered deaths one-ninth part. In the case of Wales, Monmouth, Middlesex, and Surrey, the increase has been one-eighth part. The relative weight of each observation is indicated by the additional column representing the amount of the female population of each county.

The general harmony of the results in the foregoing table, appears to be interrupted in two instances only. In the counties of Durham and Kent, the mortality of males between fifteen and thirty years of age is considerably higher than would be expected. In Durham, the excess may be due to accidents in mines; in Kent the excess may be due to deaths of boatmen, or to the omission of an excessive proportion of military and maritime population. The extremely low mortality above the age of sixty years in the county of Warwick is a deceptive appearance consequent on the omission of the ages of the population of Birmingham, which constitutes one-third part of the population of the entire county. The proportion of living above the age of sixty years is much less in large towns than in the country. If the ages of the inhabitants of Birmingham had been included in the general summary of the county, the proportion living above sixty would have been considerably less, and consequently the true mortality would have been considerably higher than the apparent. A deceptive appearance of a similar nature, though inferior in degree, exists in the counties of Gloucester and Northumberland, in consequence of the omission in the county summaries of the ages of the inhabitants of Bristol and Newcastle.

One of the most remarkable and unexpected results presented by the above table, is the fact that the mortality of females between the ages of fifteen and sixty years is greater than that of males at the same period in all cases excepting Cornwall, Devon, and Wales. The difference would be still greater, if allowance were made for deaths by accident, which are more numerous among males than among females. In Cornwall and Wales, the apparent exception may be due to accidents in mining. In Devon the apparent exception may be due to deaths in naval and military hospitals, and to a very high proportion of unenumerated sailors and soldiers. The counties of Middlesex and Surrey are excluded from comparison, because they are subject to laws of mortality peculiar to large towns. I have already stated my reasons for believing that very little error can have arisen from the understatement of the ages of females. The possible error, in comparing together the mortality of the two sexes, is to be diminished by the compensating effect of a similar

though inferior disposition in males to understate their ages. In the present table I have thought it preferable to give the apparent mortality of males between fifteen and sixty years of age, without a necessary correction for the unenumerated military and maritime population. It may, however, be acceptable to state the two classes of counties in which the defects are most considerable. Kent, Surrey, Middlesex, Durham, Cumberland, Northumberland, North York, East York, and Devon, require the largest correction. Lancashire, Wales, Gloucester, Cornwall, Norfolk, Essex, Dorset, and Southampton, require a smaller correction. The apparent results for males from fifteen to thirty, and from thirty to sixty, ought probably to be diminished by the quantity .09 in the first mentioned counties, and by .05 in those last mentioned, the reduction for all England being about .06 at each of these two periods.

In the case of Cornwall, Devon, and Wales, there appears to be some ground for the conjecture, that the relatively high mortality of the male to the female sex, arises from original peculiarity in the constitution of the inhabitants. The proportion of male to female births in these districts, differs very much from the proportion existing in the rest of the observed territory. In these districts also, the mean age at which females attain the minimum mortality, is the same as that for males; whilst in other districts, the minimum is generally attained one year earlier by females than by males. During the twenty years ending with 1830, for every 100 births of females, there were born of males, 110 in Wales, 108 in Devon, and 107 in Cornwall, whilst in the whole of England and Wales, the excess was only $4\frac{1}{2}$ per cent. In Middlesex and Surrey, the excess of male births was only $1\frac{1}{2}$ per cent.; but this affords no ground for inferring that the proportion of conceptions of males was less in London than in the country at large. The mortality in infancy is much greater in large towns than in the country; and it is very probable that the mortality of males before birth, exceeds the mortality of females before birth, according to the same law as exists for the first five years after birth. But in the case of Wales, Devon, and Cornwall, the mortality during the first years after birth, differs very little from the mortality in many countries where the excess

of males is only half as great. We may justly conclude, that the mortality before birth differed very little, and, consequently, that the excess of male conceptions is considerably greater in Wales, Cornwall, and Devon, than in the rest of the territory.

The relative mortality of the male to the female sex, between the ages of fifteen and sixty years of age, appears to be dependent on the mean age at which the period of "infancy" terminates. In nearly all the counties, this period for males terminates at the age of eight years, which is indicated by the fact, that the mortality between five and ten is 50 per cent. greater than the mortality between ten and fifteen years of age. In the majority of counties, this period for females terminates at seven years, as is indicated by the fact, that the mortality at the former exceeds that at the latter interval only 20 per cent. Cornwall, Devon, Wales, and London, are the exceptions to this general rule, the mean terminating age for females being at eight years or above. In these four districts, the relative mortality of males to females is just the reverse of what exists in the rest of the observed territory. The general law appears to be, that when the minimum is attained by both sexes at the same age, the mortality of males exceeds that of females; and that when the minimum is attained half a year sooner by females than by males, the mortality of the two sexes between the ages of fifteen and sixty years of age is equal.

In adopting the mortality between the ages of fifteen and sixty years, as an index to the healthfulness of a locality, I have been influenced by political as well as numerical considerations. The strength of any nation resides in the individuals comprehended in this interval of age. A low degree of mortality at this interval contributes greatly to the physical, but more especially to the moral, strength of a nation. A low degree of mortality in infancy does not necessarily add to the strength of a nation, because it frequently involves a high mortality at the period when life is most valuable. Comparing together two "stationary" populations having each the same number living between fifteen and sixty years, the stronger and more healthy is that containing the smaller number of living under the age of fifteen years. If, however, it is assumed that the population

above the age of sixty years, is as much a source of weakness as the population under the age of fifteen, then the physical force of any given amount of population, is independent of the law of mortality; at least the highest and the lowest laws of mortality which have been supposed to exist, yield the same proportion of living between the ages of fifteen and sixty years, out of a given number living at all ages. The highest law of mortality I suppose to be represented by the ancient tables for London and Stockholm; the lowest law by Dr. Heysham's observations at Carlisle, on the supposition that there were no deficiencies in the registered deaths.

It is a remarkable fact, that all the counties of England in which the mortality of females between the ages of fifteen and thirty is at a maximum, are situated on or near the same straight line; and that in the counties most distant from this line, the mortality is at a minimum, the maximum being to the minimum in the proportion of three to two nearly. This line is a central one running in a north-west direction from Brighton to Liverpool. In Northumberland and Cornwall, the two counties most distant from each other and from this line, the mortality is at the minimum. Sussex has been supposed to be one of the most healthy counties of England, and the mortality under the age of five years is as low in this as in any county. Nevertheless it obeys the law common to other counties on the central line, and suffers the maximum mortality between the ages of fifteen and thirty years. Possibly the apparent high salubrity of Cornwall, Devon, and Wales, may be the effect of their peculiar geological and geographical position. They are situated on primitive rocks containing no organic remains, and they are most exposed to the sea air.

In the preceding table the different counties have been classified, and the mortality has been stated for each county at five intervals of age. I now present a second table, which shows the mortality at six intervals of age, resulting from combining the counties comprehended in each of the eight classes. I also present the whole of the materials from which the mortality of those classes, or combinations of counties, has been deduced, in order that every reader may possess the means of verifying with ease the results exhibited. Any person possessing copies of the population returns of 1821 and 1831, may verify with equal facility the results exhibited for single counties. In the table for the separate counties, on account of the insufficient magnitude of the observations, the mortality between the ages of five and ten, was not distinguished from the mortality between ten and fifteen years of age, as it is in the following table.

TWO TABLES of the Living and Dying at six intervals of Age.
Living on the 28th May, 1821.

* The total registered deaths of females in England and Wales during twenty years, of whom this number was 576, which were deaths contained in returns received after the county summaries were completed. Mr. Rickman has omitted to give the means of distributing these omitted deaths according to their respective counties.

TABLE, showing in each of Six Gradations of Age, the Mortality per cent. of each Sex in each of Eight Classes of English Counties.

Class.	Males (corrected).*							Females.						
	0-5	5-10	10-15	15-30	30-60	Above 60	All Ages	0-5	5-10	10-15	15-30	30-60	Above 60	All Ages

Table of "Mean Mortality," when period of "Infancy" terminates at seven years.								4.47	.77	.65	.86	1.66	7.62	2.09

* The apparent mortality of the male sex between 15 and 30, between 30 and 60, and at all ages, has been diminished by .06 in the total, and in classes 1, 2, and 3; it has been diminished by .03 in classes 4, 5, 6, and 7; and by .10 in the eighth class.

In the above table the mortality at different ages is founded upon the deaths at specified ages occurring during the eighteen years 1813-30, whilst the absolute annual mortality is founded on the deaths occurring during the twenty years 1811-30. The difference between the mortality for the eighteen and for the twenty years is insignificant; in the former case, for the whole of England and Wales, it was for the female sex, 2.064 per cent. per annum; in the latter case it was 2.061. It would have served no useful purpose to have undertaken the labour of separating the deaths of the two years 1811 and 12, and the difficulty to the reader in verifying my results would have been unnecessarily increased. For similar reasons I have also omitted to complicate the question, by introducing a trifling correction consequent on the assumed mean population being too great, the enumeration having been made in the middle instead of at the beginning of the year 1821. It may be useful to give an example of the mode of obtaining the number representing the absolute annual quantity. In the first class, the registered deaths of females are stated to amount to 116,797, which increased one-ninth part for unregistered deaths, and divided by 20, yields 64,887, as the average annual deaths. This number divided by 363,441, representing the mean number living during the period of observation, gives the quotient 1.78, which is the number stated as representing the absolute annual mortality. The relative mortality at each age is obtained from dividing the deaths at specified ages by the living at the same specified ages. These numbers are then

made to represent the absolute mortality at each interval of age, by using, as a common multiplier, the number which will reduce the mortality of the aggregate to the number previously obtained, representing the absolute annual mortality at all ages.

In the eight classes of counties, the ascending gradations in the mortality between the ages of fifteen and thirty years, are not so well marked among males as among females. Nevertheless the difference between the maximum and minimum is nearly the same for each sex. In the first, or most healthy class, the annual mortality of females between the ages of fifteen and thirty is seven out of one thousand living; in the seventh, or most unhealthy class, it is 10.3 out of a thousand. In the same classes, at the same age, for males, the results are 7.5 and 10.3 out of one thousand living. On inspection of the above table it will be seen, that the mortality of females between the ages of fifteen and thirty most exceeds the mortality of males at the same age, when the mortality of females between five and ten differs least from the mortality of females between ten and fifteen years. From the same table it would appear that the mortality above the age of sixty years is nearly constant in all classes, especially among males. This result is not much to be relied upon, because the variations to be looked for are very small, and as such might be concealed by the population above the age of sixty years, not being exactly distributed in the same manner in the different counties. There exists, however, a distinct ground for the belief that the mortality above the age of sixty years is nearly con-

stant. In nearly all the counties of England the number living in 1821 between the ages of sixty and seventy was to the number living between the ages of seventy and eighty years, in the proportion of two to one nearly, which coincides with the result of the table of "Mean Mortality," on the assumption of the population being stationary. I have already stated my reasons for the belief that this was the case, and that the living between seventy and eighty were the survivors of the same number of births as the living between sixty and seventy years of age.

The population returns furnish the materials for determining the law of mortality in six towns only, which are of the largest size, and principally seaports. On account of the omission in the enumeration of the maritime and military population, we cannot determine the degree in which the mortality of males exceeds that of females between the ages of fifteen and sixty years. It is, however, indisputable that in all these towns the mortality of males considerably exceeds that of females at every age. In all England and Wales the mortality of males above the age of sixty years, exceeds that of females by three per cent. only; in the six large towns the excess is 14 per cent. The scale of relation connecting together the mortality at different ages in large towns differs from the scale for counties chiefly in exhibiting a high ratio of mortality in infancy and in old age; the mini-

mum mortality, or that existing between the ages of ten and fifteen years, being nearly the same in towns as in the country. The absolute mortality stated for these towns is founded on the assumption that the registered deaths are to be increased 20 per cent. in order to obtain the true number of deaths; in the whole of England and Wales, the estimated increase has been 13.92 per cent. In large towns the mortality between five and ten, is to the mortality between ten and fifteen as two to one nearly, which indicates that the mean age of attaining the minimum mortality is at nine years; for all England and Wales the minimum is attained at the age of 7½ years. This fact, which is established on the firmest ground, as it depends on the correctness of the relative and not of the absolute numbers returned, seems to contradict the commonly entertained opinion, that the epoch of puberty occurs at an earlier age in towns than in the country. It is, however, difficult to believe that such an opinion can have any sound foundation; for it can hardly be disputed that the general population of large towns suffer greater privations of food and air, than do the inhabitants of the country. Perhaps the erroneous opinion may have been founded on observations of the wealthier and smaller proportion of the inhabitants of towns who are accustomed to highly stimulating diet, and to a high temperature in their habitations.

The mode of distribution according to the age of the population living in 1821 is a question of considerable importance in the present inquiry. I have therefore constructed a table representing the number of females living in each of five gradations of age, in each of the eight classes of counties, and in each of the six towns, out of one thousand living at all ages. This table indicates that the mode of distribution of the living is nearly the same in all classes except the eighth, which represents London.

The great disproportion in this last class between the numbers living between five and fifteen, and between fifteen and thirty years of age, shows that one-third of the females living in London between fifteen and thirty are immigrants from the surrounding country. It would be difficult to give a correct and useful view of the manner in which the male population is distributed, because we are ignorant of the number and ages of the military and maritime population attached to England, whether at

home or abroad. Mr. Rickman, in the population returns of 1821, has given a very incorrect view of the distribution of the male population. He omits entirely all the maritime and military population, and consequently exhibits an excessive proportion of males under fifteen and above sixty years of age.

In comparing together two districts wherein the population is stationary, the higher proportion of survivors above the age of sixty years, will indicate the existence of a lower degree of mortality. When the population of the two districts suffers the same rate of increase or decrease, the higher proportion of survivors will equally well indicate the lower degree of mortality. Upon a principle of this nature I have instituted a comparison in the different classes of counties, and in towns, between the number living above sixty, and the number living between thirty and sixty years of age. I have added a column in the following table to represent the proportion of survivors above sixty for every one hundred living between thirty and sixty. There is a general agreement between the mortality indi-

cated by this and by other principles. For example, the annual mortality of females in the first class above the age of sixty is 7.14, and in class eight it is 9.95 per cent. In the first class the living above sixty amount to 31.6 for every one hundred living between thirty and sixty; whilst in class eight the survivors amount to only nineteen out of a hundred. The few existing discrepancies are such as might be expected to arise from occasional differences in the rate of increase of the populations compared. I have also given the results of my table of "Mean Mortality," founded upon the assumption that the population had been increasing 16 per cent. at each decennial interval under the age of fifty years, and had been stationary above that age. It has also been assumed that the age at which the minimum mortality has been attained is seven years, which corresponds with the fact for females in all England. The resulting distribution according to this theoretical table agrees precisely with the ascertained distribution according to age of the female population of England in 1821.

TABLE, showing for each of Eight Classes of Counties, and for each of six large Towns, the number of Females living in each of five intervals of Age out of 1000 living at all Ages; also showing the proportion living above 60 years of Age, for every hundred living between 30 and 60 years.

Counties.	Females in England and Wales.						Towns.	Females in Towns, &c.					
	0-5	5-15	15-30	30-60	Above 60	Prop. above 60		0-5	5-15	15-30	30-60	Above 60	Prop. above 60

The greatly diminished mortality of infants in England is probably the consequence of the rapid increase of the population during the last sixty years. There are only two principal causes which operate in producing an increase of population; and either of these would appear adequate to account for a diminished mortality in infancy, and an increased mortality between fifteen and sixty years of age. The first cause is an increased supply of food to each

living individual; of which the immediate and temporary effect is, a reduction in the mortality at every age. The second cause which determines an increase of population is, the exercise, at an earlier period, of the reproductive power, which is the only way that an increase of population can be obtained when the proportion of food to each individual remains constant. I believe that the fact will not be disputed, that the development of animate and inanimate life is

accelerated by a plentiful supply of food; and I believe that it will no more be disputed, that as the rapidity of development increases, the soundness and degree of consolidation of the mature individual diminishes. Whether a diminution of the mean age of contracting marriages causes a more rapid development of the new population, is more a matter of conjecture, as the facts bearing on the subject are yet very deficient. It appears, however, highly probable that the children of parents who have exercised the power of reproduction at an early age, will be sooner able to propagate than the children of those who have exercised this power at a more advanced age. The germs of animals may reasonably be supposed to obey laws similar to those regulating other constituent parts of adult individuals. I believe it to be admitted by physiologists, that the proportion of new matter secreted, and of old matter absorbed, diminishes as the age of the adult individual increases. That is to say, the elements of the members of young individuals are in a state of greater activity, or impressed with more motion, than those of older individuals. It may hence be inferred that the germs detached at an early age, containing elements in a higher state of activity, will have a tendency to more rapid development than the germs detached from the same individual at a more advanced age.

The English population returns, however, supply no evidence as to the epoch of puberty; they only show that the minimum mortality is now attained one or two years earlier than it is supposed to have been attained in any other European country. This is, however, a sufficient ground for presuming that the new population undergoes a more rapid development than that undergone by the population of other countries; which presumption is corroborated by a corresponding increase in the mortality between fifteen and sixty years of age. In every county of England, the mortality between the ages of fifteen and thirty years bears a higher proportion to the mortality between thirty and sixty years of age than it ought to do according to the Swedish observations, or according to the new theory of mortality. This apparent contradiction becomes a confirmation of the new theory, if it be admitted that the English population is now in a state of transition, and that the limiting age of "infancy" fifty years ago was at nine years instead of at seven and a half

years, which it is at present. It may also be admitted that the contraction of the period of infancy indicates a more rapid development, and a consequent diminution of consolidation in the new population. The deviation from the theory in England now is just what might be expected to occur, on the supposition of the rising adult population possessing a lower degree of vitality than their immediate predecessors.

The population of Belgium is apparently also in a state of transition from a low to a high mortality between the ages of fifteen and sixty years. The limiting age of infancy is now at eight and a quarter years, having previously been probably at nine years, as in other European countries. The Belgian observations exhibit the same "plague spot" as the English observations, in the high relative mortality between the ages of twenty and thirty years. The only difference between the population of the two countries appears to be, that the state of transition has endured twenty years longer in England than in Belgium. It is not improbable that the law of mortality in Belgium, at the present day, coincides with the law of mortality which existed in England twenty years ago. Under the age of ten years the mortality in England is considerably less than in Belgium; at all ages above fifteen years it is as much greater.

It might be denied that the proportion of food to each individual of the English population has been increased during the last sixty years, because the wages of labour, measured in wheat, has not been increased during that period. This objection is of no weight, because the mode of subsistence of the labouring population has experienced a great change, potatoes having constituted one of the principal articles of diet. Assuming that four pounds of potatoes are equivalent in nourishing power to one pound of wheat, and that six pounds of potatoes are generally sold for the same price as one pound of wheat, each labourer will have his command of food increased fifty per cent. In London, and probably in all very large towns, one pound of wheat is seldom exchangeable for more than three pounds of potatoes; consequently the labourer can obtain no increase of nourishment by expending his wages on potatoes instead of on wheat, and cannot satisfy his hunger with coarse food when the supply of plain food fails him. In small towns, but more especially in villages, a great increase of food is generally obtained by the substitution of potatoes for wheat. This difference in the relative value of wheat and potatoes, by causing a different degree of privation, may be the reason why the minimum mortality is attained one year later in large towns than in the country.

46, Regent-square, Dec. 1835.

THE LANCET.

London, Saturday, December 12, 1835.

It has been ordained by the Crown that Parliament shall assemble for the dispatch of business on Thursday the 4th day of February. In less, therefore, than two months from the present time, the Poor-Law Medical-Contract system, as it has been mentioned and enforced by the Government Commissioners, may become the subject of discussion in the Houses of the Legislature. Throughout the profession it is agreed, without, apparently, a dissentient voice, that nothing can be more odious, impolitic, and unwholesome, than the existing arrangements. Every where it is seen, felt, and acknowledged, that the contracts with which resident medical practitioners are forced to comply, as alternatives which are preferable to the introduction amongst them of a host of vicarious, mercenary, and unfeeling adventurers, are calculated not only to inflict upon the suffering poor a vast aggravation of their miseries, but to excite in the minds of the immense body of hale English labourers, such feelings as no wise government would deem it rational to cherish.

The system, consequently, calls for instantaneous abolition. But the Commissioners and Parliament may very justly ask, "What is the plan which is to be sanctioned as a substitute?" and the Commissioners may allege that it is not altogether fair to inflict upon them so much censure, and raise up against them such a host of enemies, unless we prove that a better system can be adopted than the one which they have sanctioned. To this point, therefore, we are anxious to invite the immediate attention of medical practitioners. Where the Unions exist, the present plan is in operation. Its pernicious effects are there observable. These should be carefully collated, and the means of subverting them by the adoption of some other plan, should be seriously considered. If

it be thought that the discretionary power which is now exercised by the Poor-Law Commissioners should be abrogated, and that the supreme executive authority, in arranging all matters connected with medical contracts, should be invested in the Board of Guardians—if, also, it be deemed an object of humane and necessary precaution, that a minimum rate of charge for the exercise of medical skill, and the supply of medicines to the sick poor, should be adopted, below which the mercenary and brow-beating jobbers should not be enabled to depress the interests of their victims, it will be necessary that a Bill should be introduced into Parliament for altering so much of the Poor-Law Amendment Act, as relates to the medical treatment of the necessitous poor.

What, then, ought to be the scale of charges?—What ought to be the minimum of charge?—Under what conditions should the Board of Guardians exercise their executive medical functions?—These questions are at this moment of great importance, and on the share of attention which may be bestowed on them may depend, in a great measure, the lives of some thousands of the people of this country. Within a few weeks it will be necessary that a plan which is sanctioned by medical practitioners themselves, for placing the medical contract system in the Unions on a just and secure basis, should be placed before the legislature. We are anxious, therefore, that not a moment should be lost in considering the question, with a view to accomplishing a practical permanent improvement; and whatever may be the views of our professional brethren on this subject, we hope that they will be induced to communicate them to us, whether for publication in the pages of this journal, or in the form of suggestions, to be employed with effect within the walls of Parliament. Quite evident is it that the cause of the suffering poor, and of the profession, will make but a sorry exhibition in the House of Commons, unless some almost unobjectionable plan can be substituted for

the system which is now carried into operation by the Poor-Law Commissioners.

What, therefore, is the scheme which medical practitioners would recommend?

IN determining to found a national University in this metropolis, the Ministers of the Crown have taken a bold step, but it is, nevertheless, one which is in perfect keeping with the liberal measures which they produced and supported in the last session of Parliament. We cannot, however, avoid expressing our regret that it is intended to grant degrees in medicine in the new institution, and this feeling, which so strongly influences our minds, is shared, we find, by the great majority of our professional brethren. *We have already in England alone, six bodies which are empowered to grant diplomas, licences, or degrees, in medicine and surgery.* It is unwise, therefore, to add to the number of those mischief-making or mystifying institutions in medicine, until, at any rate, the profession have had an opportunity of inspecting the report which is yet to be made by the Medical Committee of the House of Commons, of which Mr. WARBURTON is the able chairman.

We have not space to devote to this subject in the present number of our journal, but we may observe, *en passant*, that at a meeting of the Council of the *London College of Medicine*, it has been resolved to present a petition to the Crown, praying that no alteration may be made with reference to medical statutes or titles, until the Committee of the House of Commons has finished its labours; and, further, that in founding a new University, no monopoly may be created in favour of any particular institution or institutions.

We cannot avoid remarking that the foundation of a new University in the metropolis of the empire is a proceeding pregnant with so many important considerations, that copies of the document which is to be framed for its government, ought to be generally and

widely diffused, before the charter receive the sign-manual of the King. Had a draft of the charter of the College of Surgeons, in the year 1800, been laid before the public at that time, is it possible that so detestable an instrument could ever have received the sanction of the Ministers of the Crown? There can be no reason why the drafts of charters ought not to receive as much publicity as bills which are introduced into the House of Commons. It is to be hoped therefore, on every account, that the draft of the proposed charter will be laid before the public, so soon as the terms of its arrangement are agreed upon by his Majesty's Ministers and the Members of the Privy Council.

On the 19th ultimo the following notice was issued from the Dublin College of Surgeons:—

“Dublin, 19th Nov. 1835.

“The Royal College of Surgeons in Ireland will hold a special meeting on Monday next, at two o'clock, to receive Mr. Kirby's resignation of the Professorship of the Theory and Practice of Physic. By order,

“C. O'Keefe, Dr.”

Thus terminates, in disgrace and disappointment, a job that was conceived in the worst spirit of corruption, and carried into effect by means which cannot be safely described. May all such execrable invasions of the rights of the medical profession end in a similar manner, and may such be the just requital of all those who barter the gem of peace and integrity for the fleeting baubles of selfish and disreputable ambition. Mr. KIRBY cannot, we presume, be much surprised at finding his fate the subject of these aspirations, nor expect that the event of his improper connection with the College of Surgeons would excite in his behalf the slightest commiseration amongst his professional brethren. He walked in the “house of sin” with his eyes open. His commerce with its legends and traditions was an act of free-will and deliberate consideration. He had abundant knowledge of

the moral maxims of the place, and ought to have foreseen the consequences to his reputation of holding communion with them. He had not even the temptations to which prudence would consider it worth while to sacrifice the better feelings of human nature, and the certain results of the exercise of such abilities and information as he possessed. A professorship of the practice of physic in the College of Surgeons was at no time of much pecuniary value, and at the moment he accepted it the prospects of its becoming worth still less, were more obvious. The science of medicine had been so revolutionized in character, and so enlarged in extent, that no man in Dublin, of Mr. KIRBY's standing, nor any one who was educated in the principles of the by-gone school of physic, could expect to discharge the duties of such a professorship with success; while, to ensure the failure of such a speculation, there were arising in Dublin many young men of talent, who were instructed in, and were about to establish, the doctrines of the new school. It was not, therefore, worth Mr. KIRBY's while to accept, under any circumstances, a paltry promotion, the profits of which he might have seen would be daily diminishing by a competition which he was not indifferently prepared to oppose. It is, however, but justice to him to believe that he was the least criminal, though the most injured party, in this disgraceful transaction. He certainly was not the crafty unprincipled draftsman of a design which elaborately calculated the advantages, while it insured the ruin, of a rival, under the pretence of conferring an honour and rendering him a service. He was but the weak, improvident, consenting, instrument in a plot against the privileges and property of a whole body of private individuals, which none but the most selfish could conceive, or the most insensible to character could have executed. Both parties have, however, had their reward. Mr. KIRBY is compelled to retire from a national institution, which could only procure for him ten or a dozen guineas this season; while the

establishment which his appointment was intended to destroy, is, we understand, more prosperous this year than at any period of its former history. The humiliation of lecturing before a class of this compass, to a man who, in other days, was accustomed "his little senate to command," was the real cause of Mr. KIRBY's retirement, and not a "fit of the gout," as he would have his contemporaries and the public to believe. It was, in fact, the class of the College School which took the gout; and if we are not very wrong in our conjecture, the disease will, in a short time, become general in other departments of the same establishment. Mr. KIRBY has thus been made, by an imprudent and unjustifiable compact with a corrupt body, to quit, at the most active time of life, the busy scene, and to seek in the retirement of private life, the reparation of his once brilliant reputation. This case may be a warning to those who would follow in his footsteps. From his career, the dupe or the knave who fancies he tricks, or is tricked by, a faction, may learn this lesson, that vices operate like age; they bring on disease before its time, and in the prime of manhood disclose a character, broken and exhausted.

But the reader will naturally inquire "What was the conduct of the College, and of the individuals in particular, by whom Mr. KIRBY's sacrifice was accomplished?" Did they evince any compunction for the injustice which they committed on Mr. KIRBY, and through him on the profession? Did they even observe the dictates of decency in covering the shame and discomfiture of their victim, by passing a worthless vote of thanks, or, by any other consoling expression, approve of the conduct of a retiring officer who had suffered in their service? No; Mr. KIRBY's labours as a teacher, his favours as a patron, and his advocacy as a politician in the College School, were not considered, on the occasion of his resignation, as worth even a resolution declaratory of the approbation of that vir-

tuons and grateful Institution. The announcement of his retirement was, we understand, received by his colleagues with all that heartless indifference with which the practised seducer would hear of the miseries of his victim. The common tribute of respect which might be conferred on a porter or a clerk of the establishment—a vote of thanks—was withheld from Mr. KIRBY! Far different were the motives by which they appear to have been actuated; other objects, of more moment than thanks to Mr. KIRBY, were occupying their thoughts. "Let the dead bury the dead," seems to have been the rule acted on by them with the most literal fidelity of interpretation and malignity. The provision of a successor out of his extinction—the conjuring up a new phoenix out of the ashes of the departed, to shed a temporary lustre on the school in Stephen's-green, was a much more important matter than a vote of thanks and idle regrets; and to this point they immediately applied themselves on the occasion. The account which we last week promised to give, from a correspondent, of the proceedings, we must again postpone for a week.

In recommending, last week, the paper of Mr. EDMONDS to the attention of the profession, as a document containing information respecting many important facts relative to which great *secrecy* was observed by those few persons who are qualified to form correct conclusions on the subject, the author thinks that some misapprehension may occur, which he requests us to prevent by stating, "that the universal *silence* which "has been observed respecting materials "which have been twelve months before "the public, admits of a more satisfactory "explanation. Nearly every writer whose "opinions upon the subject are of any value, has fallen into the error of concluding, that because the annual mortality of "the English nation, at all ages, has been "diminished from one in thirty-eight to "one in forty-eight, *therefore* the mortality

"at every age of life has been diminished. "The present new material shows, that the "mortality of persons above the ages of "fifteen years has suffered no diminution; "the mortality of infants alone having been "diminished. It may not, therefore, be "reasonable to expect, that writers of mortality will assist to disseminate newly-presented facts, which are contradictory "of their previously-expressed opinions." "The concluding portion of Mr. EDMONDS's article will be found at page 407 of this week's LANCET.

METROPOLITAN UNIVERSITY DEGREES.

To the Editor of THE LANCET.

SIR,—Being at present a student at *King's College*, and intending at some future period to present myself before the examiners of the university about to be founded, as a candidate for a degree in medicine, I consider myself to be partially interested in the question which has been discussed on in the article at page 389 of *THE LANCET*, to which my letter is intended as a reply, viz., Should residence for a given period in an university, and conformity to a prescribed course of study, be required to render a person eligible to graduate in the University of London?

But before proceeding farther I must premise, that although I am aware that you yourself advocate the principles which your correspondent has laid down, yet I am not deterred from writing, through any fear that my communication will be rejected solely because it is opposed to your opinions. No, Sir, I have long been a reader of *THE LANCET*, and never do I remember having seen an instance of illiberality on your part. I therefore forward this to you, relying on your known candour for its insertion, as much as if I knew that you cordially agreed with the opinions expressed in it. Neither indeed (considering it as a matter of policy) would it be wise to confine the columns of a scientific journal to the use of one party; for its reading being confined to men of a liberal education, who are accustomed to judge for themselves on every subject, and unbiassed in their sentiments, they never form a decided opinion on any point without weighing well all the arguments, *pro* and *contra*. With such readers, therefore, no object can be attained by refusing free discussion on any matter.

The object of your correspondent apparently is, to admit persons to an examination for degrees, without subjecting them to a previous course of study, and merely on

The strength of a certificate of good moral character. With the proposition that a certificate should be required, I most cordially agree, but some important alteration ought to be made in the manner of obtaining it, for the deplorable facility with which certificates are now given is well known. Indeed, I have no doubt that they are frequently forged. What I now proceed to prove is, that although the scheme of allowing young men who are designed for a profession to obtain their education where and how they choose, might be better for a very few individuals, it would be almost ruin to the great majority. At present, when students, from a fear of being refused their certificates, are compelled to attend lectures occasionally, how many are there, let me ask, who never show themselves in a lecture-room more than three or four times a week? Perhaps your correspondent will say that they are more profitably employed in pursuing their studies at their own homes; but this I am afraid will scarcely ever be found to be the case. No, I am ashamed to say that even under the present laws, a great number throw away that time on vice of every description, which ought to be spent in study. But still, owing to the lecture-system, they are compelled occasionally to recur to their studies. Now, if these persons were allowed to study in what manner they liked, the consequences clearly would be dreadful. They would most likely be sent by their relatives to London or some large town, where, instead of studying, they would squander away their money and time in the pursuit of dissipation, always putting off the period of study until, having entirely ruined themselves in fortune and health, they have disgusted their friends, and, in many cases, are compelled (*heu quanta de-gradatio!*) to apply themselves to trade, and perhaps linger out the remainder of their miserable and degraded existence in the employ of some chemist and druggist. Such is a feeble picture of the evils which I am satisfied would in numerous instances result from the misjudged act of leaving young men to chalk out for themselves their mode of study. Students, especially of medicine, are always, partly from inexperience, and partly from bad companions, prone to vice, and this measure would, I am afraid, give them more opportunity for it. Such are my objections, treating this in a moral point of view.

Again, I am confident that to a certain extent the oral has a great advantage over the written method of communicating instruction to youth. There are many points connected with the different studies which it would be impossible to treat of fully in books, although there is no doubt but that if a person were to hear a number of lectures, without reading at the same time on the subject, they would benefit him

very little; and there are also many matters of general information connected with the subject of the lecture, which he hears at the lecture, and of his knowledge of which it would be next to impossible for the examiners to form an idea in an examination of any reasonable duration. Also the weekly examination of the different classes by the several professors, is an advantage of no small importance.

Also let me suggest, that it is unfair to cast imputations on a body of men whose names are not even known, and who are not yet called into I may say political existence, which your correspondent does in hinting that the old method of study has been adopted by them as likely to be more conducive to their own ease.

Again, he says that none but the comparatively rich will be able to graduate in this University. Certainly not, and therefore it is so much the more to be approved of. All graduates are, at present, as a matter of course, supposed to be gentlemen, and to be either of good families, or to have received a polished education, fitting them for the society in which, as graduates, they are entitled to move. Now, if young men were to be allowed to graduate directly on coming to London, relying solely on their own exertions for getting through the examination, and without being put to any expense, being sons of farmers, tradesmen, &c., their graduation would detract much from the respectability of graduates as a body, and though, in a few instances, no one could object to persons raising themselves from the lower classes by their talent, still, as a general thing, it cannot be too much deprecated.

Being fearful of exhausting too much space, I must now draw this subject to a close. I have not, I hope, said any thing which can be construed as personally offensive to any one. As to the strength of my arguments, as compared with those of my opponent, that must be decided by the public.

I see that in your last number a correspondent would suggest, that the new body be allowed to confer degrees in surgery. Permit me to suggest that if this be carried into effect, a regulation should be made compelling candidates for the degree "chirurgie baccalaureus" to afford proofs of understanding drawing, as I am of opinion that this knowledge assists the anatomical student greatly. Also, that if a graduate in surgery, or, in fact, if any graduate, wishes to obtain the license of the Apothecaries' Hall, he should be exempt from the regulation which requires an apprenticeship of five years, and should only be obliged to spend one year in dispensing.

Allow me also to draw the attention of your readers to the fund at present raising for the support of the mother and sister of

the late Gilbert Burnett, Esq., lecturer on Botany in this institution. They depended entirely on his exertions for their support, and are now in a state of poverty. He was the last male descendant of Bishop Burnett.

I would also propose to the proprietors of King's College, and the University of London, i. e., the institution at present called so, that they should admit two young men annually in each department, giving them free admission to every class until they have completed their studies in the particular profession they make choice of. The objects of election should be young men of good connections, but destitute of the means of placing themselves in a profession, or giving themselves an education which might fit them to conduct themselves with credit in the society in which by birth they are entitled to move. This should, if possible, be kept secret from their companions.

Why should not the new University be empowered to confer a degree in architecture? Surely it is a science. The degree might, to avoid confusion, be *Coryphaeus*,* to rank as high as *Magister*, and be taken two years after that of *Bachelor of Arts*. Anxiously expecting the publication of your next number, I remain, Sir, your obedient servant,

A KING'S COLLEGE STUDENT OF
MEDICINE AND SURGERY.

THE WITHHELD MEDICAL-REFORM-ESSAY
PRIZES.

To the Editor of THE LANCET.

SIR,—I have read with equal surprise and indignation, in THE LANCET of Nov. 21st, the letter of Dr. Epps, on the subject of the medical reform essays. A more flagrant breach of faith to the writers of the several essays which were so many months ago transmitted to Dr. Epps, it is impossible to conceive, than the statement contained in that letter, that "the Committee of examination have decided that there are not any three of the essays deserving of the prizes." On referring to the original conditions, published with the signature of Dr. Epps, as secretary to the Medical Reform Association, I cannot discover any reference whatever to the *abstract merits* of the essays. They simply state, that "For the best essay will be awarded the sum of 50*l.* sterling; for the second, the sum of 30*l.*; for the third, the sum of 20*l.*" It was the comparative merits of the essays alone, then, that the Committee of Examination had to

decide upon. With their *intrinsic* merits, so far as the prizes were concerned, they had nothing to do; and how little meritorious they might be, provided the proposed conditions were attended to, the *three best* were as much entitled to the prizes, as if they had actually come up to the *beau ideal* of perfection which the Committee now assume as necessary to render them "deserving of the prizes."

Of Dr. Epps I know nothing, but as an honourable member of a liberal profession I am sure it must be extremely painful to him to be made the medium of communicating to the public so dishonourable an instance of broken faith. That Mr. Hume can have sanctioned such a proceeding, I am unwilling to believe, but as the treasurer and only declared member of the Committee of Examination, he will do well to use his influence in obtaining justice for the writers of the essays.

It would be easy to dilate on many circumstances connected with the proposed prizes of the Medical Reform Association; more especially the great delay that has taken place, — without any explanation, — the promise which Dr. Epps formerly made of an early decision, and the extraordinary effrontery with which further competition is invited for prizes which unquestionably belong to writers who have already contended for them. But, in the hope that a feeling of shame will induce the Committee to perform, without further delay, an act of justice which they must perceive to be inevitable in the end, I shall for the present forbear.

I remain, Sir,
Your obedient servant,
PHILO-JUSTITIA.

APOTHECARIES' HALL.

To the Editor of THE LANCET.

SIR,—An instance having very recently occurred under my own observation of the treatment of students at Apothecaries' Hall, I am induced to forward the facts to you, in order that students may see the necessity of strictly adhering to the regulations of the Hall, however difficult of performance and mysterious they may appear.

A pupil who had entered to all the required lectures (*perpetual*), presented himself at the Hall, for examination in Latin, but being wholly ignorant of the form of registering, he had omitted to register during the time usually allowed. To obviate this he was advised to address a petition to the Board of Examiners. He did so, and was told to call upon the Secretary (Mr. Watson) for an answer. This he has repeatedly done, without obtaining any information on the

* "Coryphaeus" means the Master, Chief, or Principal, in any thing. The degree, therefore of "A.C." could not lead to any confusion, while that of "A.M." might.

subject; and no answer can be got, although I know for certain that his petition was laid before the examiners, and leave was decided in by them to be given to the gentleman to register. On one occasion he asked Mr. Watson what he had better do. Mr. W. said, "I know nothing about the case. I am no more than a post-office to the Hall. You have your answer and there's the door." He then applied at the Hall, but was again referred to Mr. Watson, upon whom he called, in my presence, for the tenth time; but on giving his name and stating his business, Mr. W. said that no such petition as his had ever been sent, and when I told him that I saw the petition in his (Mr. W.'s) own hands, a few mornings previous, he declared that my statement was false; and when I told him that we had been under the necessity of calling eight or ten times within three weeks, he said it was all "a lie," and that he had never seen either of our faces before. And this is all that my friend can learn of his petition. Is this the language which ought to be used by the Secretary of the Apothecaries' Company, to students praying for information? Of his ungentlemanlike conduct I will say nothing, as it is only what students must expect in that neighbourhood. But he should remember that although he is Secretary to a Company who derive a great income by the contributions of students, he may live to see the abolition of that Company, as the result of the combination of those students with the thousands of practitioners who are already rendering their powerful influence to place medical education under the superintendence of a very different body of men. I am, Sir, your obedient servant,

A MEDICAL PUPIL.

December 5th, 1835.

*. The name and address of the writer of this letter have been placed in our hands.

TERM OF APOTHECARY-APPRENTICESHIPS.

To the Editor.—Sir,—I cannot forbear noticing the very extraordinary conduct of the Examiners of the Apothecaries' Company, in making so many alterations in the regulations for apprentices. When I was bound apprentice, about eighteen years ago, I was distinctly told that it was necessary I should serve the whole seven years, prior to my attendance at the London hospitals. Two years after the expiration of that time, being established in practice, I took an apprentice, and was then told that the Court thought the seven years too long, and that they would be content with five years' *actual servitude*; it now appears that they consider three years sufficient, which is surely unjust to those who have been compelled to serve the whole term; and though I certainly think the term of seven years, which I

served, much too long, yet, as it was the customary time allotted to all, I had no reason to complain, and reflected that I should in my turn derive benefit from the assistance which my apprentices would afford me during the latter part of their stay. According to the present regulations, medical men are expected to dispense with the services of their apprentices just at the time they are beginning to be most useful to them, and the pupils are compelled to attend a tedious routine of studies, subject to such complicated regulations as are exceedingly annoying and harassing to them, and reflect the utmost disgrace and discredit upon the Court of Examiners. Trusting you will allow insertion to these remarks, I am, Sir, your obedient servant,

A LICENTIATE OF THE
APOTHECARIES' COMPANY.

TREATMENT OF FRACTURES.

To the Editor.—Sir,—The scientific observations of Mr. Radley on the treatment of fractures in late numbers of your invaluable publication, bring to my recollection the practice I witnessed when assistant to Mr. Clapham of Thorney, who has now been in the habit, for upwards of thirty years, of invariably treating fractures on the same principles as Mr. Radley. His sons, I understand, pursue the same plan. It is to be regretted that men of such long standing in the profession, and who have enjoyed such opportunities of gaining professional knowledge, do not communicate to the public some of the many valuable cases which must necessarily have thus come under their observation.—I remain your ardent admirer,

M. D. W.

Borough, Dec. 4, 1835.

MEDICAL MAGNETISM.—To the Editor.—Sir,—In the report of a meeting of the Westminster Medical Society, published in your valuable miscellany of the 5th instant, it appears that Dr. Epps thought proper to state "that a gentleman had offered to Messrs. Watkins and Hill of Charing-cross, 100 guineas, if they would produce magnets having the like power (referring to those prepared by Dr. Schmidt). They tried, but at last were compelled to acknowledge their incompetency." Now, Sir, we trust you will afford us space to give the most decided contradiction to that statement. Why our names should be thus thrust forwards to advance the views of Dr. Schmidt, we know not; but this we do know, that neither with the Doctor, nor with his magnets, are we in any degree acquainted, nor have we ever made any attempts to compete with him. Hence it is clear that Dr. Epps must have been labouring under some strange delusion

when he made the assertion, to which, in justice to ourselves, we have been compelled to advert. We remain, Sir, your obedient servants,

WATKINS and HILL.

5, Charing-cross, 8th Dec., 1835.

NOTE FROM DR. SCHMIDT. — *To the Editor.* Sir, I am anxious to reply to your question in the last Number of *THE LANCET* "if Dr. Schmidt withholds any information relative to his mode of constructing magnets," in the negative. It will be obvious to you, that in making known the chemical theory upon which I construct my magnets I furnish the clue to similar results which are equally attainable by others. Having found what I consider the right path, I point it out to the scientific world. Need I do more? I avail myself of this opportunity to thank you for the full and favourable report which you have given of the discussions at the *Edinburgh Medical Society*, on mineral, or, as you properly term it, medical magnetism; and to ask you if any reports of cases of cure by the magnet will be acceptable to you? If so, I should feel obliged by the publication of two or three complete ones, which I can authenticate. I am, Sir, your very obedient servant,

CHARLES SCHMIDT.

137, Regent street; Dec. 9th, 1835.

* * * If Dr. Schmidt transmits to us, for publication, any cases which have occurred to him since his residence in London, we will certainly endeavour to find room for them in our columns.

CORRESPONDENTS.

THE note of *Argus* is the product of a malicious mind. We believe that the private lecturer whom the writer attempts to vilify, discharges his duty more effectively and scientifically than any other private teacher in the metropolis. One thing is curious in connection with the medical schools of the metropolis. Candidates, it is well known, are not admitted to examina-

tion at the medical colleges and halls, unless they produce certificates of attendance in some of the "recognised" schools. It is equally well known, that in many of the schools no information whatever is obtained by the pupil, but that he gets the whole of his knowledge from some teacher who discharges his duties to his class at his private residence. Now when a candidate who is known to have been the pupil—whether an inattentive one or not, — of a private teacher, happens to be unsuccessful, all the "recognised" gentry, and many of their idle pupils, exult at the defeat of the rejected party, and in their tumult of joy the lecturers often forget that the rejected person had been their own pupil during more years than he had been of the private teacher during as many months. In other instances, parties who rejoice may be moved in their exultation by even less worthy feelings. A private lecturer, in cases of the rejection of his pupils, is wholly exonerated from blame, unless it can be proved that the competency of the candidate was certified, — either orally or in writing, — previous to his application to the medical boards to be admitted to an examination.

Will *Humanitas*, of Rochester, whose communication was inserted in *THE LANCET* of Nov. 21st, favour us with his name and address? The one first sent has been accidentally mislaid. Will our correspondent object to his name being communicated privately to a gentleman who is actively interesting himself in an attempt to improve the medical arrangements in the Unions?

The communications from Mr. Way, the K. Street School, and very many other communications, as well as our last reports from the societies, are all unavoidably postponed for a week.

LECTURES

ON

DISEASES OF THE BRAIN AND NERVOUS SYSTEM,

NOW IN THE COURSE OF DELIVERY IN THE UNIVERSITY OF PARIS.

By M. ANDRAL,

Physician in Chief to the Hôpital de la Pitié, and Professor, and Lecturer on the Principles and Practice of Medicine, in the Faculté de Médecine of Paris.

LECTURE IV.

ENCEPHALITIS.

TO-DAY, Gentlemen, we propose passing in review the several symptoms by which inflammation of the brain is accompanied. The greater part of them, as you shall presently see, consist in certain modifications of the phenomena which depend on the life of relation. We shall commence with the most striking, those which cannot escape the notice of the most common observer. Many of these symptoms are produced by a greater or less trouble of nutrition. Let us examine them first briefly, and take up, to begin with,

Lesions of the Functions of the Digestive Apparatus in Acute Encephalitis.

In many individuals affected with encephalitis, we do not observe any appreciable functional derangement of the digestive tube; but in the great majority of cases it is the seat of disorders more or less severe; and the digestive apparatus presents to us several notable troubles. And first of vomiting and nausea, two of the most striking symptoms by which the commencement of inflammation of the brain is frequently disclosed. Here, as in many other circumstances, the symptom has its seat in the stomach; but the real cause of the phenomenon is situated in another and a far distant organ. Vomiting, and at least nausea, very frequently precede the onset of acute

encephalitis. Sometimes the vomiting is observed only at the very commencement of the disease; sometimes it persists for several days, or even during the whole course of the malady, the patient throwing up an enormous quantity of bilious matter, or being unable to taste a drop of fluid without occasioning nausea, and rejection of the contents of the stomach.

In a great number of cases, also, we remark another symptom connected with the digestive tube, which, like the former, is an effect of sympathetic influence, propagated from the centre of the nervous system, and not a sign of disease in the canal itself. This is constipation of the bowels; a phenomenon very frequently accompanying the different forms of encephalitis. In many cases it is carried to the highest degree, and alvine evacuations are obtained only by the most powerful drastic purgatives, or the condition of the intestinal canal resists altogether any means that we can employ to overcome it. The vomiting, nausea, and constipation, of which we now speak, are frequently the only lesions of nutrition that the patient may present. The tongue generally remains natural (we suppose the disease without complication), clean; the abdomen indolent and free from pain, rather contracted than tumified, or tympanitic. It is of the highest importance to pay due attention to these latter symptoms, for the derangement of the stomach, especially when connected with headache, may very readily impose on the physician. The presence of vomiting &c. when it coincides with a natural state of the tongue and abdomen, and, above all, with the absence of meteorism, is a sign of the greatest value, to distinguish at an early period those nervous symptoms which depend on an idiopathic irritation or inflammation of the brain, from typhoid and other dangerous febrile affections, where the lesion really occupies the mucous surface of the digestive tube. These are the principal lesions of the functions of the digestive passages which present themselves in cases of encephalitis. Let us now turn to

Lesions of the Circulatory Apparatus.

The disorders produced by inflammation of the brain on the circulatory apparatus are

lated by M. Gendrin; it is as follows:—"A young man, fifteen years of age, had bathed twice in a river on the same day; after coming out the second time he lay down on the bank and fell asleep, without his hat, exposed to a burning sun; on awaking he was perfectly speechless, though he was able to walk home, apparently in good health. He was bled and purged, and recovered his speech next day, but lost it again, at intervals, during the three or four following days. He was dull and heavy, and complained of the back of his head; after a few days more, he had squinting and double vision, with obstinate constipation; pulse 60. After farther bleeding, &c., the pulse rose to 87; but he gradually became comatose, and died twenty-five days after the commencement of the attack. After death, the substance of the brain was found, in general, highly vascular, and a very considerable extent of it was in a state of ramollissement, mixed with suppuration. The ventricles were distended with fluid, and the membranes, in many places, much thickened."

This is a remarkable case of inflammation of the brain, where the first symptom was a sudden loss of speech; and remark, that the injury does not seem to have existed more towards the anterior lobes of the brain than any other point, though many physiologists would there place the power that governs the production of the voice. In many other cases, the first accidents are not seen towards the brain, but commence in the organs of nutrition. We all of us know how frequently meningitis is announced by vomiting. The irritation of the brain is propagated to the stomach, and gives rise to irritation and rejection of the contents of the latter, before it has lasted sufficiently long to produce actual inflammation of the former organ.

The Duration and Termination of Acute Encephalitis.

These are very variable. In some cases the disease terminates rapidly in death: the patient does not survive the commencement of the attack more than twenty-four hours. In other cases the march of the disease is more slow; it may be prolonged to thirty or forty days, or two months; but if the patient continue to show symptoms after this latter period, we must consider him as labouring under the chronic form of the disease. The termination of encephalitis is not less variable than its duration; the patient may recover, and then his recovery is either perfect or imperfect; in the latter case, the troubles which remain are generally connected with movement. Some patients conserve a strabismus for a greater or less period; others present a contraction of one or several fingers; finally, others are affected, for a long time after the subsidence of inflammatory symptoms, with a well-marked

diminution of sensibility in some one part of the body. Let us now turn our attention to

The Treatment of Encephalitis.

The first, and most pressing indication, is the abstraction of blood, in proportion to the intensity of the disease, the constitution of the patient, &c. Here the rules are precisely the same as those we laid down when treating of cerebral congestion; it is, therefore, unnecessary to insist, at any length, upon this point, particularly as we have abundance of matter to occupy the time allowed for the present course.

After copious and repeated bleeding, we have a second means, which has frequently been employed with the most decided benefit in cases of encephalitis and other inflammations of the parts within the cavity of the cranium; this is the application of cold directly to the patient's head,—a powerful remedy when cautiously administered, but it requires a good deal of care and judgment. A grand principle in the application of a low temperature, in cases of cerebral inflammation, is to withhold this means until such time as the febrile reaction has been brought down by sanguineous emissions, and other similar remedies. If the disease, indeed, has commenced without any remarkable acceleration of the pulse, increased heat of skin; in a word, without fever; then we may have recourse to cold at a much earlier period. However, its application is always attended with two inconveniences, that render its management difficult. In the first place, if the inflammatory reaction has not been sufficiently reduced, by the means we have pointed out, before the employment of cold, we run a great risk of aggravating the symptoms instead of calming them. In the second place, the effect of cold, at a low temperature, is, in many cases, to throw the patient into a state of prostration and collapse that is very alarming. In some instances, the patient, shortly after ice has been placed on the head, has sunk into a state of collapse and even coma, which have been dissipated with the greatest difficulty, or terminated in death. You must, therefore, pay especial attention to this point, and when you employ cold, take care not only to see that all febrile reaction has been previously subdued, but, still more, watch your patient with care, and on the first appearance of prostration, reflect how far this symptom may not be an effect of the powerful remedy you have applied. Perhaps this latter inconvenience is more to be dreaded than the former. In the one case you can subdue the symptoms of renewed febrile action by antiphlogistic measures; but in the second it is often a matter of the greatest difficulty to recover the patient from prostration into which

Let us now consider the different ways in which cold may be applied. These are various. The first and most common is the application of ice to the head. It is essential that this should be done in a permanent manner; the temperature must be kept constantly at the same point. A temporary reduction of temperature is more likely to occasion the reaction we have already spoken of, than to produce any benefit. The ice should be pounded, and care must be taken that it does not incommode or irritate the patient by its weight. It is also necessary to warn you that cold may have very different effects on the sensibility of certain patients. In some cases when we place the ice on a patient's head it gives rise to a most unpleasant sensation that is supported with difficulty. Sometimes this goes off; in other cases it persists, and may become so distressing as to compel us to abandon the remedy altogether. In other cases, on the contrary, the sensation produced is of an agreeable and soothing nature. As the temperature descends, the symptoms of excitement vanish; the agitation and delirium disappear, and the patient recovers the full exercise of his intellectual faculties.

Instead of ice, some physicians prefer the employment of cold affusions, at a temperature varying from 22°, to 18° or 16° (centigrade). We can rarely have occasion to go below the latter; it is quite sufficiently low for every practical purpose. The affusion is performed by pouring water, at the temperature just indicated, for the space of two or three minutes on the patient's head, after which we cease. This may be repeated once or twice during the day according to circumstances. Sometimes we prefer establishing a constant current of cold water on the patient's head; or, finally, in other cases, we may follow the example of those who evert the water guttatin, drop by drop, from a short distance above the head; by this means the temperature is gradually reduced, and the effects which result are often of the most encouraging nature. Not long ago, I had occasion to see a young person who was labouring under all the symptoms of acute inflammation of the brain. We had recourse to the use of cold, under the form now alluded to; water was allowed to drop slowly on the patient's head, and a complete recovery took place. This case was attended in conjunction with M. RECAMIER, and remark, that no other active treatment of any kind was employed, although the disease presented itself with symptoms of a very severe nature.

I could cite numerous other cases which establish the efficacy of cold as a means of relieving cerebral inflammation; but it is necessary that you must know how to manage. It must be applied as it is a dangerous remedy, and all other powerful remedies must be given to a certain degree of expe-

rience to determine in what cases it is applicable, and how far it may be carried.

Finally, we may employ cold under another form, viz. in that of general ablation. The different modes of applying a reduced temperature will depend partly upon the predilections of the physician, partly upon the specific object he may have in view; but, on the whole, we may conclude, that cold is a therapeutic agent to which we may often have recourse with advantage in cases of encephalitis, and that in whatever form it is employed the results cannot fail to be beneficial.

Revolusives are another very useful class of remedies in the treatment of inflammatory affections of the brain. We may apply them in the form of blisters or sinapisms to the lower extremities, the neck, behind the ears, or over the whole surface of the head; but, bear in mind that it is only at certain periods of the disease, that we ought to have recourse to cutaneous irritants, viz. when the symptoms of reaction have been completely subdued by sanguineous emissions, or by cold. However, let me remark, that some patients will not bear the application of revulsives to the skin; in many cases the action of a blister has been sufficient to bring back all the symptoms that were dissipated by a previous blood-letting; the agitation recurs; the patient is seized with convulsions, and paralysis, or relapses into a state of coma, immediately after the cutaneous nerves are stimulated by a sinapiam. I am, therefore, very sparing of this form of revulsives in cases of encephalitis, although in many particular cases their utility is incontestable. Thus, when the coma persists for a length of time, when the sensibility of the skin is excessively obtuse, when the eye is insensible to light, and the pupil remains without movement, we may have recourse to energetic revulsives with advantage, in the hope of stimulating the powers of life, which seem on the point of becoming extinguished. This is a practice which is very successful amongst children. On the contrary, when the heat of the skin is elevated, when the pulse shows symptoms of reaction, when the erythema of the brain is betrayed by excessive agitation or delirium, then I would abstain altogether from the employment of a means which would in all probability but increase the existing degree of irritation. In cases of this kind I prefer addressing the revulsives to the intestinal canal, provided we have no signs of irritation or inflammation in the abdominal cavity.

When the belly is indolent and free from pain, the tongue clean and moderately humid, I have no hesitation in administering active purgatives, with the design of promoting a derivation from the brain to the surface of the digestive tube. Several authors partake of this opinion. Thus, Dr. ABER-

CROMBIE (and I quote from his work in preference, because it is filled with highly interesting and useful observations) says, "In all forms of the disease, active purging appears to be the remedy from which we find the most satisfactory results; and although blood-letting is never to be neglected in the earlier stages of the disease, my own experience is, that more recoveries from head affections of the most alarming aspect take place under the use of very strong purging, than result from any other mode of treatment."

We have now to notice another remedy which has been counted as a true specific in inflammation of the brain by many writers; this is *mercury*,—a means once looked up to with the utmost confidence in the treatment of encephalitis and several other inflammatory affections. In a question of this kind it becomes my duty chiefly to lay before you the result of my own observations, and this I shall endeavour to do as briefly as the subject will admit. Mercurial preparations are employed under two principal forms to combat inflammatory affections of the brain; the first is in the form of frictions, which are usually practised either on the sides of the neck, or behind the ears. I must confess that I never saw any decided advantage obtained from the administration of mercury under this form. You can readily conceive that inflammation of the cerebral substance is a disease requiring the employment of remedies whose action is prompt as well as decisive. Now mercurial frictions have the great inconvenience of requiring a certain length of time for the introduction of the remedy into the economy, and before this the inflammation may have assumed a fatal character. Perhaps this form may be innocent, but it is one which does not merit any particular confidence. The other form, and it is a far more general one, in which mercury has been administered, is internal, and the preparation selected, by almost universal consent, is calomel.

You are all acquainted with the prominent part which calomel has played in the treatment of inflammatory disease, especially in the various affections of children; but here an important question suggests itself. Is calomel, as has been said, really a specific remedy in certain inflammatory disorders, or is its action rather to be referred to the purgative effects which follow its administration? This question can only be answered by a careful observation of facts. Go, then, into the hospitals, and observe what passes there; or, if you have already had occasion to follow several cases of inflammation of the brain, reflect upon the phenomena you have witnessed, and you will find that in all the fortunate cases the administration of calomel has been followed by decidedly purgative effects. We may

therefore fairly doubt whether the result did not rather depend upon this action on the intestinal canal, than upon any specific attribute. The predilection generally shown by practitioners for this preparation of mercury may be accounted for upon other grounds. Calomel is an excellent purgative, and suitable to a great variety of cases. It does act in an irritating manner on the digestive tube; and, from its insolubility, it does not communicate any bad or nauseating taste; this latter circumstance is not without importance in diseases of the brain, where we should avoid every cause of irritation; it is particularly important in all affections accompanied by delirium, where we often have the greatest difficulty in inducing the patient to take the necessary medicaments. Let us now pass to the consideration of

Chronic Encephalitis.

Here the observations we have to make will be brief, for the disease bears a close resemblance to the acute form which we have just terminated. The *anatomical characters* of chronic encephalitis are nearly the same as those we have given for the acute stage. However, induration of the cerebral substance more frequently accompanies the former than the latter. We also more frequently observe, as a consequence of this variety, the formation of abscesses in the substance of the brain, of cysts with strong, fibrous, well-organized parietes.

The *causes* of chronic encephalitis are the same as those which determine the acute form; and it may precede the latter, or succeed an imperfect cure. The *symptoms* also are the same; they consist almost exclusively in lesions of intelligence, of sensibility, or of motility; the march of the disease, however, is different, and it is in this circumstance alone, that we are to look for the differential characteristics of the two forms. In the chronic form the symptoms succeed one another more slowly. The intelligence remains intact for a more considerable period; the lesions of mortality are more uncertain, and the disease terminates either in a sudden exasperation of the accidents, or by producing a profound though gradual influence on the different acts of organic life.

Chronic Inflammation of the Cerebellum.

There is one part of the brain, which, as we before remarked, is but little subject to attacks of acute inflammation, but which oftener presents traces more or less well marked, of having been the seat of the chronic form. This part is the cerebellum. We might perhaps be able to collect from eight to nine examples of chronic inflammation of the cerebellum, where the lesion was simple, that is, granular, and without any similar lesion of the other parts of the brain. The analysis of these cases

variety of symptoms accompany the disease in this portion of the nervous centre. The most striking phenomena certainly are connected with motility: here we observe the principal lesions. In many cases paralysis has been noted as affecting the superior or the inferior extremities; the seat of the paralysis is indifferent; we are not able to establish a greater frequency in the pectoral, than in the abdominal members. In other cases the power of the muscles seems merely weakened; the patient's gait is vacillating. In one single case the patient suddenly fell down. In other cases, however, we do not observe any lesions of movement; it is the sensibility which presents more or less remarkable modifications. Thus in two cases, the prominent symptom was a very acute sensibility of the whole skin, and after death an abscess was found occupying one of the lobes of the cerebellum. In one case the only lesion of sensibility consisted in an acute pain in the occipital region. In one case observed by Dr. GALL, the predominant symptom was blindness. We have already noticed how blindness is connected with several diseases of the cerebellum. This is especially noticed in cases where tubercles have been found imbedded in the substance of this part of the brain. It is not easy to explain the reason of so remarkable a phenomenon. Does it depend on the connection of the cerebellum with the pons varolii, and, consequently, with the fifth pair of nerves? Or are we to look for an explanation in the communication between the cerebellum and the tubercula quadrigemina, from which latter you know the optic nerves partially arise? These are mere conjectures. Finally, in one case of chronic inflammation of the cerebellum, the patient was troubled with a constant nausea only.

Such are the symptoms that usually accompany chronic inflammation of the cerebellum. How difficult it is to attach them to any general principle, or to say why at one time the same lesion should merely produce nausea, at another blindness, and at a third loss of speech! In many of the cases we have alluded to, the symptoms almost seem to be individual, and any attempt to generalize them in the present state of our knowledge would be hopeless; perhaps this may depend upon the small number of observations we possess; let us then examine more, and let us hope, for the honour of science, that at some future time we may be enabled to explain this diversity of symptoms by the different points of the organs which are compromised in the disease. For the cerebellum this explanation is much more easily given than for the cerebrum; in inflammation of the former, the principal derangements, as I have just remarked, are obtundement of motility, and you observe the connections which unite the cerebellum and spinal marrow.

Our remarks upon the treatment of inflammation of the cerebellum, shall be very short indeed. It is precisely the same as that for encephalitis in general; the main remedies being sanguineous emissions, cold, and revulsives.

ST. THOMAS'S HOSPITAL.

CLINICAL LECTURE

ON CASES OF

ABSCESS IN THE PERINEUM,

Delivered in the Session 1835-6,

By MR. TRAVERS.

GENTLEMEN,—There are, I think, no cases under my care of more profitable observation at this moment than those of fistula in perineo, of which there have been and are now several here.

This abscess of the perineum takes place under very different circumstances. We often have it quite independent of the urethra, as we have abscess in the neighbourhood of the anus perfectly independent of the rectum. Local causes contribute to the formation of an abscess here. The injury of a blow, the irritation of a tight dress, an over-long ride or walk, and fatigue of any kind, may set up a local congestion and a phlegmon here, which becomes an abscess in the perineum. It occurs in the cellular tissue, like a common abscess, having no tendency to communicate with the urethra, which is perfectly sound and healthy. A full-sized bougie will pass readily into the bladder, and there may have been no previous affection of the urinary organs, but it is always important to open abscesses situated near canals early.

An abscess abutting on a canal should have both an early and a free opening, to hinder the inflammatory action from proceeding in the direction of the canal, or you will find it very difficult to prevent a sinous communication between them. The sinus may not be direct, but indirect,—not large, but small,—and the patient, after some days, when all seems to be going on well, voids, at first a few drops, and then a small stream of urine, from the perineal opening, which prevents it from healing. The case is very simple, and is far from being uncommon.

The treatment is very simple. Having ascertained that the urethra is pervious, and that nothing is the matter with it, treat the abscess as a common abscess, only with the greater promptitude, on account of its situation. Lose no time in leeching and poulticing, provided the evidence of matter is fairly perceptible. Rather, indeed, antic-

pate than delay the operation, by making a free and deep incision; and in that way you will be very likely to save the urethra.

A very common cause of a second class of cases is an inflammatory condition of the lining membrane of the urethra, which has supervened upon gonorrhœa. You know that an inflammation of the cells of the spongy body of the urethra is a simple and acute gonorrhœal inflammation. You know that *hernia humoralis*, as it is called,—swelled testicle,—is a constant cause of gonorrhœal inflammation. You know that spasmodic stricture may exist to such an extent as to cause perfect retention of the urine for two or three days, and inflammation of the neck of the bladder, which creates such excessive and distressing pain in the act of micturition. You know that these are all consequences of inflammation of the lining membrane of the urethra, not confined to the original seat of the gonorrhœa, which is within an inch or two from the extremity of the urethra, but translated from thence to the bulb, the membranous part and the prostatic portion of the urethra,—all this being the result of neglect, or imprudent conduct,—venereal excitement, and other such causes. Thus inflammatory irritation and spasmodic stricture of the lining membrane of the urethra follow gonorrhœa, which produces, by local contiguity, inflammation of the sheath, and the parts surrounding the sheath, of the penis, and the parts situated in the perineum.

Another class of cases is that in which you have not spasmodic stricture of the urethra, but permanent stricture. Now here, although the stricture is imperfect,—not such as to prevent the person from parting with his urine, but such as admits of his parting with it slowly, with difficulty, and under preternatural exertion of the muscles which assist to empty the bladder,—there is an increased determination of blood to the neck of the bladder, and all the parts connected with it during the operation; and the frequency with which persons are called upon, under such circumstances, to void their urine, occasions great aggravation of their sufferings. There is an habitual straining in the act of micturition, and all these circumstances predispose to the contiguous inflammation, and the probable supervention of suppurative inflammation in the perineum.

Now the inflammation in these cases commences externally,—that is to say, although the inflammation of the urethra, the stricture, whether spasmodic or permanent, and the consequences attending it which I have mentioned, cause and aggravate the mischief in the perineum by determining blood to the parts, yet the abscess occurs externally without any direct communication, originally, between it and the

passage. Such a communication, however, is more likely to happen in cases in which there is an inflammatory condition of the urethra itself than in the first class of cases, where, as I stated, the urethra is sound and unaffected.

Besides these, you may have another class. You may have, together with permanent stricture, adhesion, forming crevices, of the membrane,—false passages—suffering small portions of the urine to pass out of the canal, more commonly taking place behind the stricture. Where the stricture retards the urine, a dilatation of the canal occurs, caused by the impulse of the muscular action to force the urine on; and by reason of this constantly recurring, a fissure or crevice at length takes place, through which a small quantity of urine permeates, remaining there for years with little or no inconvenience. In an old strictured patient, you will find half-a-dozen false passages, not, perhaps, caused by the bad management of a surgeon, but produced by disease. There is no danger of extravasation following their creation, for they are so defined by the artificial cuticle produced by the adhesive inflammation which is instituted from the moment that the lesion or wound takes place in the lining membrane, that extravasation will not follow. An opening on the anterior side of the stricture is generally the result of wrong treatment,—of a false direction given to a bougie,—not the result of the *ris-a-tergo* of the urine, from the action of the muscles in emptying the bladder. Anterior openings are found to be contrary to the direction in which the urine passes, and the disposition of the crevice or lesion which is so made, is less likely to set up bad symptoms. False passages are thus continually made with impunity. You may readily appreciate the difference between the natural lesion which takes place as the result of permanent stricture on the bladder side of the stricture, and that which would take place in consequence of the penetration of the walls of the urethra by the bougie. In either case, however, I say, the artificial opening is made with comparative impunity, provided it be of small extent; but, in either case, if it be large, or if the condition of the urine, of the parts of the constitution, be such as to be likely to carry on an inflammatory action, then, instead of adhesive walls forming for the passage of the urine, the parts will take on the suppurative process; and abscess will result.

Now when you have once got abscess, you cannot answer for the consequences. There is pus, which must be got rid of, either through the urethra or through the incisions, and this will be followed by inflammation, a foreign and a bad matter at the same time introduced, and the urine is the most dangerous agent in the abscess,—keeping up the suppurative inflammation,

stimulating the sloughing, producing gangrenous inflammation, and then a free penetration, on all sides, of the contents of this abscess, into the surrounding loose cellular texture of the perineum, there being nothing to oppose a resistance to an indefinite extent of extravasation.

An abscess in the prostate gland being confined within the sheath or fascia which contains those parts, will discharge itself after having produced a complete retention of urine. I have, on one occasion, passed a catheter below the prostate gland, when it has contained matter, and the urine has flowed, after the evacuation of half a teacupful of pus, proving that there must have been an immense abscess there. In such case, the whole inflammation has been confined to that one spot, and has terminated there, like an abscess of the wall of the intestine, within the canal; but this is very rare, and never happens, I think, in these parts, except in abscess of the prostate, in the portion of the urethra anterior to the neck of the bladder. If matter forms in the parts forming the body of the penis, then extravasation will be the result, and the existence of gangrenous inflammation is known by the decomposed state of the pus, and the fever it presents on being discharged.

If in such cases the stricture be impermeable, so much the worse, because the disease will be the more troublesome. But the abscess may be combined with, or depending simply on, a bursting of the urethra, the result of accident, and without any disease. This happened to the late Lord CLARE. While leaping a ditch his horse stumbled, threw him forward on the pommel of the saddle with great violence, and burst the urethra. He became a patient of Mr. CRINE, who performed the only operation that could be employed in that case,—that of dividing the parts freely, and connecting the ends of the urethra to an elastic catheter, and the case did very well. I have heard one of his own family detail the circumstances, as well as Mr. CRINE.

The effect of extravasated urine is to destroy the cellular tissue in all cases. But though you have a bluish indicating inflammation, in parts that are favourable to the extravasation, yet it becomes a question whether the extravasation has extended to the parts so discoloured, or whether the discoloration is merely a symptom of that sympathetic inflammation which the common cellular membrane takes on in the neighbourhood of some other portion that is diseased. In one of the worst cases that we have had lately in the hospital, there was considerable discoloration of the abdominal groins which was not attended with any general gentlemen entered the hospital, and both the cellular substance of the integuments of the penis,

and the cellular membrane covering the muscles of the abdomen, had admitted the urine, and that, consequently, all those parts were condemned to undergo the sloughing process. However, I gave it as my opinion, having often seen such before, that that would not be the case, believing it to be only a sympathetic inflammation of the neighbouring cellular membrane. This matter is of great importance as regards the result, and my observation proved to be just in this case. The man got perfectly well after the operation was performed. The simply inflamed spots suppurred freely on being opened, there being no dead substance at all in them, the puriform matter being perfectly healthy, and although sinuous communications existed between the abscesses, they healed up kindly, as soon as the matter was discharged. This could not have been, if there had been any sinuous communications of extravasated urine; because, as I said before, I never yet saw, in a vast collection of cases, a case in which the cellular membrane did not die to the full extent of the extravasation of the urine, and was not cast off in the form of a slough.

The necessary operation, where an abscess has not communicated with the urethra, consists merely in freely opening the abscess. Where it is connected with stricture of the urethra, it is right to take up the treatment of the stricture as soon as convenient, after having discharged the abscess. I should, however, be in no hurry to attend to this, if the person passes his urine freely; I would rather provide for the full and free discharge of the abscess. But, in a case of impermeable stricture, whether with or without abscess, the operation of cutting down upon it, and dividing the urethra at the point of the stricture, becomes necessary. In hospitals, cases of extravasation occur very often, though cases of imperforate stricture, justifying the operation, occur but seldom. Yet I must say, that when they do occur, they do, according to my experience, perfectly well. In some of them you cannot introduce the slightest instrument with any justifiable degree of pressure. You cannot pass the best adapted metallic instrument into the bladder; even a small probe would not pass the stricture. In such cases the operation of cutting down upon the stricture becomes absolutely necessary. You place the patient in the position for lithotomy, and freely divide the strictured parts with the knife,—the parts not having been changed, observe, by extravasation of urine, or the surrounding external inflammation. I am supposing that there is nothing more the matter there than the impermeable stricture. The operation is then not attended with any considerable difficulty, the anatomy of the perineum not being altered by inflammation or extravasation. The object then is to pass first a metallic catheter

into the bladder, substituting for that, as soon as you can, an elastic gum catheter. In the case of the bursting of the urethra, you are to proceed in the same way, and to connect the two ends by an elastic gum catheter.

In the case of extravasation of urine, which will sometimes happen almost suddenly,—in the course of forty-eight hours,—from the neglect, for instance, of a perineal or a scrotal abscess, the scrotum may become oedematous, swelling very rapidly, becoming almost as large as it is possible to imagine, and as black as your hat, the patient being in a very bad way, in short, dying. Long before such a state arrives, and as soon as it is ascertained that the urine is making its way from the bladder into the cellular substance, there should be a free incision made along the line of the perineum scroti to the whole extent of the extravasation. If the scrotum be not implicated, of course it is not necessary to divide it; if it be, it is right to divide it, and to do so upon the line of the raphe. There the freest discharge is produced, the most equal and uniform. By laying open the integuments on either side of the raphe of the scrotum, you do not obtain so uniform a discharge as by taking the central line; and the incision may be made there with the greatest depth, freedom, and safety. The relief that follows, the enormous draining of purulent urine, or urinous pus, and the quantity of layers and shreds of cellular substance that are discharged, is miraculous. You need not be solicitous of bringing the ends or the extremities of the urethra finely together; that is a matter of little importance. It is far better to put the patient to bed. You do not pass a catheter after cutting for the stone. In that case you have no fear of extravasation; nor need you where you have a large opening made, partly by nature and partly by art, and in the line of the urethra and the perineum. The occasion is analogous to that of mortified hernia; you have no occasion to go about seeking for the ends of the mortified gut; in fact, you had much better not do so. You had better spare your labour, for the ends are placed in better apposition by nature than they can be placed by you; and, as to the stricture, the effect of that is entirely removed by the free division and the exit you have given to the slough. So, in the case of extravasated urine, having discharged the bladder, which you do by making an incision of several inches length into the scrotum, and of a depth sufficient to remove the urine and morbid contents; it is labour in vain to look after the canal. You will find that after the urine has secreted, it comes away with the greatest freedom. The mischief is already done, and you can adapt the treatment of the case, with reference to its final purpose, much more advantageously when the bladder has

recovered itself, when it has lost its irritability, and when the sympathy between its suffering state and the system is at an end. Indeed the relief obtained from a free discharge of urine, as compared with a very imperfect and difficult discharge of that fluid, is inconceivable. The fever then subsides, and there is no longer any difficulty in passing an instrument, for the fact is that half the wall of the canal is deficient, and you have only therefore to take the direction which you know the canal should have. It must be, in part, an artificial passage.

So soon as the sloughs have been thrown off, the granulating surface begins to show itself on the sides of the wound. Wait for that; wait until the system has rallied, and availed itself of the relief afforded by the operation, and then you will have no difficulty in passing an instrument, and in keeping it in the bladder. But do not attempt to pass one before. The difficulty will lessen just in proportion as the process of filling up and healing goes on. If you do not attend to this you protract the good effects of the operation, for to pass the instrument is a proceeding of great difficulty, owing to the old sinuses which have formed in some cases, and to the totally altered and thickened condition of the perineum and the cellular membrane. It is often a very difficult matter to find the extremities of the urethra, and you do not dilate the urethra without considerable risk. A case occurred not very long ago, which some of you may remember, where a narrow-bladed straight knife was carried in the direction of the bulb of the urethra, behind the arch of the pubis, towards the bladder, to dilate the stricture when the patient seemed to be on the point of recovery. This was followed by a venous hemorrhage which, though we could not control it, and would by no means, under ordinary circumstances, have been sufficient of itself to cause death, yet in the very exhausted state of the patient, did terminate life. The dissolution could only be attributed to that. However, it was a bleeding over which we had no control. Probably it was the vena profunda that was wounded. A plexus often lies at about the back of the bulb and prostate. Upon examination it was found that the knife had taken the direction of the bulb, onward to the bladder. I have seen a person for an hour, or an hour and a half, or for nearly two hours, suffering the most dreadful agony, which may be got rid of as soon as you have given a free discharge to the extravasated urine and the sloughs, and in so doing you provide for the ready and immediate discharge of the urine.

Well, then, there is another way of your placing an instrument, and that is, tallic or otherwise, at any time you perform the operation, never happens that the bladder will not be at

hat time. You have first to remove the irritation, by using the instrument you set up inflammation of the lining membrane, which goes from muciform to puriform, and aids in suppurative inflammation, probably terminating in the destruction of the entire mucous membrane of the parts, besides setting up the irritation which you ought to subdue. I have so often found it necessary to remove the catheter, which has been introduced at the heels of the operation, but I am quite sure that in all cases it is wrong to introduce it, except where you are operating on undiseased parts, such as in bursting of the urethra, for in the latter cases it is important to introduce an instrument, and there is no reason on earth why you should not; but the same argument that holds in favour of the practice in the one case, tends to favour the converse practice in the other. Certainly, it is not right to introduce any instrument where the parts are broken up by disease. Finally, let me repeat, gentlemen, that a free urethral incision is the proper remedy against the danger of that extravasation which is evidently threatened where the patient cannot pass a drop of urine, and you are unable to relieve him in any other way against that consequence.

I may just name to you, that in one of the cases in the hospital, the formation of perineal abscess, without the smallest tendency to extravasation, was proved, by the perfectly permeable state of the urethra. The man was operated upon for the abscess at the time the urine was passing. In another case, also, in which the incision was made, both cases being cases of abscess following gonorrhoea, there was no stricture, and the instrument in that case also passed freely into the bladder. A third case was one which came under the care of Mr. South, when I happened to be out of town, where there was retention of urine, and where the operation of dividing the stricture was very successfully performed. This was a case unattended with extravasation; it happened in a man named Jones, who now passes muciform and not purulent urine, and who is getting better. The other was the case of a man who had also abdominal abscess. A free division of the raphe scroti et perinei was made in that case for extravasation. The incision was both extensive and deep, and the patient went out perfectly well.

CLINICAL LECTURING.—I do not know any human contrivance that can more effectually oblige a medical officer to study carefully the case of his patients, and at the same time to be cautious in the remedies he prescribes, and himself under the necessity of giving an account of every case in a public manner.

NORTH-LONDON HOSPITAL.

CLINICAL LECTURE

ON CASES OF

GONORRHOEA, POISONING FROM ASENIC, IDIOPATHIC ANASARCA, AND PERICARDITIS.

Delivered in the Session 1835-36,

BY DR. ELLIOTSON.

GONORRHOEA IN THE FEMALE.—*Creosote*.—The first patient to be spoken of to-day is a French girl, admitted on account of gonorrhoea. It appeared from her own account, that she had caught gonorrhoea several times. There was a very considerable discharge of a darkish colour, and slight swelling of one of the labia. She said that she had been labouring under the disease now for many months, but had been much worse within the last five or six weeks: she had very probably caught it afresh. She was ordered two drops of creosote in an ounce of water every four hours. The dose was increased to four minims, then to six, and then to eight minims. I gave her this, because I had heard that creosote has considerable power in gonorrhoea. For myself, I have had no experience of it in this affection, but I thought the account probable, because turpentine has always had considerable reputation in gonorrhoea after the inflammatory state was over, and creosote is very analogous in many of its properties to turpentine. During the whole time she was labouring under gonorrhoea, she had suffered with pains of the head, and bones of the legs and arms, as well as in her shoulders and back. At the same time that the creosote was ordered her, she was directed to have a warm-bath every day. This treatment was begun on the 12th of August, and on the 29th it did not appear that the discharge was diminished. I myself have never seen any internal medicine do good in the gonorrhoea of females, excepting where the case was inflammatory, and antiphlogistic measures were had recourse to; but I have always seen the greatest advantage where the inflammatory stage was over, and also in leucorrhoea, from the employment of an injection of the nitrate of silver. I am not satisfied that internal remedies are of the least use either in leucorrhoea or gonorrhoea, excepting so far as they overcome the inflammatory state, if the state be inflammatory, and so far as tonics, if required, may act by strengthening the body, but I have not seen gonorrhoea itself controlled by any tonics, astringents, or specifics, given internally. There is, however, a local application, which is, I believe, recommended by many practitioners, and which has,

I think, far greater power over gonorrhœa and leucorrhœa than any other local application, where there is no inflammation; and that is the nitrate of silver. Some females will bear two, three, or more grains to the ounce, but it is always better to begin with a small quantity. I myself am in the habit of beginning with a quarter of a grain to an ounce of water. This I ordered for her. At the same time that this was commenced, the dose of creosote was increased to nine minims. On the 5th of September she complained of great bearing-down pain, said she felt as if the uterus was falling through her, but on examination by Mr. TAYLOR no prolapsus or other morbid state could be detected. On the 10th, the pain was much diminished, and the pains in the head and back were much less. She said, however, that the vulva was very sore; though on examination nothing could be found the matter with it, and she was discharged on the 15th of September, without my seeing any reason to believe that creosote had been useful.

In the inflammatory stage of gonorrhœa, it is necessary that the person should live upon very low diet, and remain as much at rest as possible. The greater number of cases of gonorrhœa become so violent as they are, through the patient's inattention to diet on the one hand, or not resting the body on the other. Walking about, and especially walking up and down stairs, is most injurious in this complaint, and, I believe, that very few persons would have a severe inflammatory gonorrhœa, if they would remain perfectly still, and take nothing but diluents,—at the same time employing such antiphlogistic measures in the way of blood-letting as the symptoms require. Cupels will often arrest the disease at once, if given within the first forty-eight hours, but after that time it has comparatively but little power; whereas, after the inflammatory symptoms have subsided, copaiba has very great power over the disease, and whether turpentine be employed or copaiba, it should not be until after the inflammatory symptoms have subsided, and I presume also that not until then should creosote be given either.

POISONING FROM ARSENIC.—The next case is one of poisoning from arsenic in a girl aged 22. About three hours before her admission she had swallowed, intentionally, an ounce of the arsenic of commerce in some beer. Ten minutes afterwards she became very sick, and on its being discovered, from something adhering to the sides of the pot, that she had taken poison, a medical man was sent for, who gave her an emetic, the effects of which having subsided, she was brought to the hospital. Mr. TAYLOR immediately evacuated the contents of the stomach, by means of the stomach-pump, and then administered lime-

water and chalk-and-water. There was a good deal of burning pain in the stomach during the night, but on the morning of the 14th of September, she was nearly free from pain. She was afterwards ordered to be bled to a pint, for the next morning it appeared that she had suffered a good deal of burning pain in the night. But that had almost entirely subsided. As she fainted when eight ounces of blood were taken, no more were drawn. The blood presented no morbid appearances. On the 15th she had some pain in the stomach and bowels, and slight tenderness. "She says that her legs and arms feel as if something were gnawing them. There was more tenderness at the large end of the stomach than at any other part of the abdomen. The tongue was much furred; the pulse 100 and weak; no appetite." No other treatment was adopted except that of cupping her between the shoulders, and on the 23rd of September she went out perfectly well.

When arsenic has been taken, the first object, if possible, is fully to evacuate the stomach; but after every particle of the poison may be supposed to be withdrawn, frequently much further treatment is required. Arsenic, like many other poisons, is a strong irritant to the stomach, and produces gastritis while it exerts its poisonous effects; and very frequently after all the poisonous effects have ceased, the patient suffers considerably from the inflamed state of the stomach, and bleeding, generally or locally, is absolutely necessary. Sometimes, after other poisons have been taken, there is more or less gastritis, rendering the lowest possible diet necessary, and frequently many repetitions of blood-letting, either generally or locally.

IDIOPATHIC ANASARCA.—The next is a case of idiopathic anasarca. This was the case of a French woman who laboured under anasarca, and was under the care of Dr. THOMSON. Just before her death she was exceedingly anxious to be under my care, and made herself very unhappy that she was not, and Dr. THOMSON was so obliging as to gratify her wish, and she was taken under my care, only, however, to die in about a week. I could discover no sign of organic disease about her, unless the constantly albuminous state of the urine, which had been observed from the time she entered the hospital, made it probable that there might be some disease of the kidneys. The anasarca I believe had come on gradually, but no particular affection of the chest or abdomen could be discovered,—no disease of any organ. About two days before her death, when she was in extreme debility, an attack of hæmoptoe of the chest came on, and the lower part of the chest was the seat of sharp pains indic-

pleura, and there was, likewise, crepitation, indicating inflammation of the substance of the lung. This was very certain, and soon after there was a dull sound on percussion, and deficiency of respiration at the lower part, but she was far too exhausted for me to think of bleeding her, or dosing her with mercury. Indeed, I felt satisfied that nothing could do her good. Blisters, merely, were applied. She sank and died. I mentioned before opening her, that we should find the ordinary marks of inflammation of the pleura and lung; and that at the lower part of the pleura, we should find flakes of lymph and a quantity of serum. These you will recollect were discovered, and the lower part of the lung was found gorged with blood, so as to be in the first stage of inflammation. All these were recent effects. No disease, however, of any part could be discovered, except in the kidneys, and these, as I suspected, were found diseased, but only to a very slight degree. Very minute granules were seen in them, nothing like so numerous as are generally seen, and far more minute. I cannot myself imagine that the dropsy was occasioned by the state of the kidneys. It appeared to me to be a disease of the cellular membrane throughout, like many cases of dropsy which are called idiopathic. The disease of the kidney, in my opinion, could not account for her having gradually sunk, or for the dropsical symptoms. An albuminous condition of urine, I many years ago pointed out, does not indicate, necessarily, that there is organic disease of the kidney, nor is there the slightest proof, in my mind, that it indicates any affection or disease of the kidney at all; for it will appear suddenly in persons who take cold and have inflammatory anasarca; it will go away as they are bled, and as the anasarca is cured. To suppose that the kidney is organically diseased in such cases is impossible, and that it is the effect of inflammation or congestion of the kidney, is mere assumption. But I have no doubt that where the urine is constantly albuminous for a great length of time, in dropsy, there usually is organic disease of the kidneys, which is generally attended by albuminous urine, though albuminous urine need not be attended by a diseased condition of the kidney. Indeed, some persons make albuminous urine when they take certain articles that cause indigestion.

In those cases of chronic dropsy which are not inflammatory, and which are unaccompanied by any organic disease, or any organic disease that will explain the dropsy, I really believe the affection to be one of the cellular membrane, and I have no doubt that very minute investigation with the microscope, and an accurate mode of anatomical dissection, weighing given volumes of the organs, would discover

that it was in a state of disease: but I myself have not had time to make these investigations.

PERICARDITIS.—The next case had been a well-marked case of pericarditis, which disease was entirely removed before her admission. The patient, a woman, aged 29, was admitted on the 29th of August. At the end of the first week in October, the report at her admission was, that "she had menstruated sparingly, and with great pain, this being the first appearance of the catamenia for seven weeks. A week ago she was seized with difficulty of breathing, pain in the chest, increased on inspiration, and a short dry cough. She had a severe shooting pain in the cardiac region, which went through to the left shoulder and down the arm as far as the elbow. There was also great tenderness over the cardiac region, on pressing the ribs down hard; and on pressing between the ribs, and also pressing up against the diaphragm. The action of the heart became rapid and irregular. There was extreme pain in the region of the liver, the lips were livid, the tongue was brown, and there was globus hystericus. She was bled three times in the arm. Thirty leeches were applied to the side, and she took the mercury to pyalism. This treatment produced considerable relief."

Now, it is at this period of life—that is to say just before puberty, to the end of the young adult age, that pericarditis principally takes place. It occurs most frequently, I should say, between the ages of 10 and 30. No case could be better characterized than this. There was pain in the region of the heart, shooting up to the shoulder and down the left arm as far as the elbow. It is very common for the pain to stop at the elbow, and I have seen it in many cases stop an inch short of the elbow. In other cases it will run down the whole arm, and stop at the wrist, and in many cases I have seen it stop an inch above the wrist. It has been said by Dr. ANDRAL, that pericarditis occurs frequently without pain. I believe it frequently occurs without pain, according to the patient's account, but I have never yet seen a case which I have suspected to be pericarditis, or which was proved after death to be pericarditis, in which I did not discover pain upon examination, that is to say, on pressing down upon the pericardium, or pressing up against the pericardium below the cartilages. The action of the heart is generally rapid, as it was in this case. Here it was irregular. It does not always seem to be irregular; sometimes the pulse is found to be full, and sometimes it is very small. Now the treatment that had been adopted before her admission, appeared to me to have entirely removed her complaint, at least so far as have subdued it, that no continuation or

repetition of the measures then used were necessary. She was in a state of extreme debility, her pulse was 106, but the local symptoms appeared to have given way so considerably, that I had very little doubt that if she was kept perfectly still, and allowed nothing but the mildest food, she would do well. I therefore contented myself with ordering her gruel, barley-water, and a pint of milk a day. Her gums were tender with the mercury which had been given, and her bowels were relaxed; she was therefore directed to take two ounces of chalk mixture after every loose evacuation. The gentleman who treated her before she came into the hospital (Mr. BRYANT), was a clinical clerk here a few months ago, and he seemed to have made the diagnosis with great accuracy, and to have treated her actively and exceedingly well. In fact, in all probability, her life was saved by his treatment. She went out on the 15th perfectly recovered, no medicine having been given to her after her admission, except the little chalk mixture to restrain the action of her bowels.

CASES OF

DISEASE OF THE HEART.

ELUCIDATING CERTAIN

DIFFICULTIES OF DIAGNOSIS.

By JOHN FOSBROKE, M.D., Physician to the
Roxs Dispensary.

“*La méthode de l'auscultation à sans doute éclairé beaucoup le diagnostic des maladies du cœur. Elle donne souvent de très-utiles et d'indispensables renseignements, et on ne doit jamais négliger d'y avoir recours. Mais seule, et sans l'aide des autres signes, elle ne pourrait que rarement révéler d'une manière certaine l'existence de ces maladies, pas plus qu'elle ne peut, dans un très-grand nombre de cas, découvrir seule l'existence des tubercles du poulmon, ou même d'une inflammation aiguë de cet organe.*”—PROFESSOR ANDRAL.

BEDDOES wrote, in 1808, his excellent “Letter to Sir Joseph Banks” on the necessity of medical reform in this country, and pointed out the great strides which the French physicians were making in pathology and other branches of medical science, in consequence of the abolition of the old university schools, and the medical and surgical corporations, by the decree of Aug. 8, 1792, for they were close, illiberal, and corrupt; at the same time recommending, in 1803, the adoption of the present system, which was open, liberal, and anti-exclusive. About that system, which has constituted, as a whole,

the most perfect form of medical government in Europe, he had no difference with the French in 1807, and afterwards at M. Lavoisier's, in Paris. When they had formed their establishments anew, he wrote to Dr. Berger, of Geneva, to complete his knowledge of the subject, and also concerning those other universities on the continent which were newly revived about the same time, “ours alone,” as he observes, “standing still, a stupid uniformity being the vice of all old universities.” Beddoes (if I recollect rightly the information given by Mr. Higgins, of the Dublin Society, who was his assistant) was the professor of chemistry at Oxford, and he entertained the vain hope, to quote his own words, that “the day when a certain set of notions was to be thrust down the throats of society by mere party-praters, the owners of every monopoly, and their clerks in office,” was over, and he proposed to “raise the brows of the parsons, the country gentlemen, and the merchant-princes, in every part of the kingdom,” in behalf of medical reform. But Beddoes was driven from the head citadel of monkish bigotry and prejudice, for the premature liberality of his opinions, and taught that the spirit of the English universities might resemble those of France previously to their dissolution; for “the spirit of the universities,” he said, “was at variance with the spirit of the age, and the spirit of the body of the universities was at variance with that of many of their most able members. The country was becoming enlightened; whilst those who studied with the intention of becoming public instructors, found themselves, upon leaving the University, where they had been educated, behind the world in many respects, and forced, as it were, to unlearn every thing, in order to commence their education anew. This was a state of things that could not last long, and the catastrophe was hastened by doctrines which, though long in openly manifesting themselves, and though opposed by all the influence of church and state, were not destined to be slow and ineffective in their ultimate progress.” “These ancient and venerable institutions were, it is true, destroyed by the revolution, but they had been denounced by public opinion, and the spirit of the age, for thirty years before that event,† and now fell as the natural consequence of the spirit being wrongly directed, and reform not being conceded in time.‡ Beddoes, although, until towards the premature close of his days, influenced somewhat too much by his imagination, was not one of those men who obtain a character by mere censing, and the interested voices of incompetent judges, but a man of
